All physisists (not teachers) are opinion that in space is enough matter to
propagate the electric waves.

>If empty space were filled with electrons,

In "empty space" is ISM (interstellar medium = ions, electrons and dust)

>we would be able to measure the drag caused by the electrons. Any known
>particle of matter with a rest mass would cause a drag on movement of
>matter through it.

Michelson discovered in 1887 and 1925 that ISM rotate with the Sun and do not rotate with the Earth.
Meteorologists know that above the equator is steady wind caused by ISM.
In the rest of the globe the winds are caused by many factors.

Michael wrote: "In the end for almost all amateur radio operators it does not matter one
wit how an antenna works. It most certainly matters if it works and how well."

But the all of you are "the infinite sink" of the real information for me.
Not all Amateur radio operators are teachers.
Faraday and Marconi did not go to schools.

Utter nonsense.

You are a babbling idiot.

> Faraday and Marconi did not go to schools.

Faraday attended lectures given by the Royal Institution and Royal Society.

Marconi was educated privately in the lab of Augusto Righi, in Florence
at the Istituto Cavallero and, later, in Livorno. He also studied under
Augusto Righi, a University of Bologna physicist.

You are a babbling idiot.

Szczepan, you were told in a previous posting (4th June) that Marconi was educated privately.
" ... Marconi was educated privately in Bologna in the lab of Augusto Righi, in Florence at the Istituto Cavallero and, later, in Livorno. As a child Marconi did not do well in school ...".
Why do you still say that Marconi did not go to school?

I'm not sure about the "all" but indeed in space is enough matter to propag=
ate the EM waves. But it is DARK MATTER, consisting of a different kind of =
matter with which none of us are presently familiar. Dark matter particles =
possess a certain observable mass but are clearly not electrons. The densit=
y of electrons in free space has been sampled by space probes and there's s=

imply not enough electrons to support EM wave propagation in free space.

Do yourself a favor and concentrate on discovering what the "sea of dark ma=
tter" is all about. Dark matter is estimated to occupy 84% of all the matte=
r in the universe and one thing is certain - it is not leptons of which ele=
ctrons are a group member.

> Electric current creates magnetic field, oscillating electric
> current creates oscillating magnetic field and not
> "electromagnetic wave" as current belief. Electron has a standing-

electric field and magnetic field at right angle (watch video structure of electron). The flow of electrons in a conductor is essentially caused by the attraction between the electric fields of mobile electrons and "fixed" positive charges in the conductor. Oscillation of electrons in a conductor is caused by the alternation of electric polarity in the conductor. Because of electric field and magnetic field of an electron is at right angle, when oscillates the electric field of the electron will be parallel to the oscillation and magnetic field will be perpendicular to the oscillation.This oscillation of the electron creates transverse wave on its magnetic line and the oscillating magnetic line is radiated to space.

What's the diference betwee an photon and an electron?
http://www.quora.com/What-is-the-difference-between-a-photon-and-an-electron
   ... an electron is a tiny particle that has an electric charge, and
   a photon is a tiny, massless particle that we can perceive as
light.

http://van.physics.illinois.edu/qa/listing.php?id=2348

> Q: Why are photons (all wavelengths) considered to be instruments of the so-called "electromagnetic force"? So far as I know, please correct me, photons have no electrical charge nor are they influenced by magnetic fields. The term "electromagnetic spectrum" seems to me to be very inappropriate and highly misleading.
>
> A: Grahame- You're right that electromagnetic waves, whether viewed classically or in terms of quantized photons, are not affected by static electrical or magnetic fields. They have no charge. Nevertheless, they do exert electrical and magnetic forces on charged particles and magnetic particles. Viewed classically, they consist of nothing but electrical and magnetic fields

> propagating through space, so it's entirely appropriate to call them electromagnetic waves. ...

Photons are little units of light -- they are the original "quanta" of quantum mechanics. Their existence was hypothesized to explain the details of the photoelectric effect -- photons with enough energy can knock electrons out of materials. Since then, photons have been found to play a central role in the explanations of many physical phenomena, from explaining how much heat is radiated by hot objects to modern quantum cryptography.

But on to your question! The classical model of electricity and magnetism makes use of the ideas of electric and magnetic fields. Maxwell's equations describe how these fields behave, and the Lorentz force equation, which describes how the fields push and pull charged particles and magnets. A prediction of Maxwell's equations is that there are waves in the electromagnetic field which travel at the speed of light. These waves were identified with light by the experiments of Hertz and others. We therefore have two very different ideas for how light works -- as waves in the electric and magnetic fields, and as motion of particles -- photons. This pair of explanations is called "wave-particle duality" and is a recurring theme of quantum mechanics. Depending on the experimental situation, light acts as a wave or as a particle (but never both simultaneously).

Weirder still -- static electric and magnetic fields also exhibit wave-particle duality. The collision of a charged particle with another (repulsive or attractive) can be modeled as the exchange of photons and you get the same answer as if you had calculated everything with just the classical fields (in the limit that the classical calculation applies -- slow incoming particles). The quantum calculation involving the exchange of photons is more accurate in describing actual collisions at higher energies.

And now the really weird part. You might ask -- "Photons travel in straight lines at the speed of light. Why doesn't the electric field of a charged object just zoom away at the speed of light?" It turns out that the photons which make up a static electric or magnetic field are "virtual" -- their energy and momentum doesn't satisfy the relationship for "real" photons -- E=p*c (E is energy, p=momentum, and c is the speed of light). The virtual photons are constantly emitted and reabsorbed. A charged object with an electric (and possibly also a magnetic) field is surrounded by an entourage of photons, constantly being emitted and reabsorbed.

Photons, real and virtual, are emitted and absorbed by charged particles, even though they are not charged themselves. They only interact with charged particles, and not with each other. That's why photons don't interact with magnetic fields -- the photons which make up the magnetic field are not charged so other photons cannot interact with them.

Technical p.s.: photons have entourages of electrons (and other stuff) around them, and so photons can interact with other photons by interacting with this cloud of charged stuff. The effect is so small it hasn't been observed yet for low-energy photons. Very high-energy photons produced in particle accelerators may collide with themselves readily.

Tom

Follow-Up #1: photon sources

Q:

...and how does a photon (real or virtual) carry or represent the information about the charge (eg +/-) that it's interacting with?
- Paul (age 57)
UK

A:

It may be easiest to describe this in terms of classical electromagnetic fields, which already contain the essential ingredients. Charged particles are sources of these fields. The way in which charged particles give rise to fields is captured in the Maxwell equations. Charge itself gives rise to a 'divergence' in the electric field. Current gives rise to a 'curl' in the magnetic field. However, looking at the fields in some region does not give all the possible information about the sources. For example, a static field might come from a little nearby charge or a lot of far-away charge.
Mike W.

I conferred with our local guru on this matter, professor Michael Stone. He thought about it for some while and then said 'It's tricky'. His explanation is that an ordinary, free, photon has two different transverse polarization states as can be easily demonstrated by the usual crossed polarizers experiment. An electron that interacts with this kind of photon couldn't care less where it came from. It just scatters ala Compton. Now in the case of when the photons are virtual, such as when two electrons are close to each other and are experiencing Coulomb-like forces, the photon has an extra, longitudinal, polarization state. This extra state carries information as to the charge sign of its source. Hence the electron receiving the photon can decide whether to be attracted or repelled.

rec.radio.amateur.antenna
metal dector for barbed wire fences

Anybody here have any suggestions for possible ways to detect fence wire, mostly 1, 2 or 3 levels of barbed wire but also some 8 inch square matrix? Typical mounting would be on a tractor or trailer, so the detector would need a sense of direction, ie looking outward not inward. Minimum range would be around one foot with 4 feet probably optimum.

Typical retail metal detectors have a short range and need a metal free environment, leaving the methods they use somewhat doubtful. Evidently, there are detectors with seperate heads/coils and 1-5 foot ranges but, once again, require a metal free environment.

One possible area would utilize rf antenna's, one transmiting and the other recieving a reflection from the wire(s). A parabolic or corner reflector type antenna maybe if not for the high frequency - two 12 inch antenna's would be about max size and that's in the gigaherts range, which might be a problem.

Any suggestions along this line will be appreciated.

Hul

If there is a free end accessible you might try feeding some rf into it and then following along with a receiver to detect the underground portions. This may or may not require strong attentuation at the receiver antenna -- using a short loop or something across the input.

If there is one level. chances are you may find others underneath with a little digging unless there are accessible ends to them whereas tracking the RF would work just as well.

Just a wild and maybe not so crazy idea of how I'd try for a quick cheap fix.

Good idea.  RF tracking works very well for buried cables and should work
for fence wire.  I used it some years ago when we were adding antennas to an
existing field and needed to know exactly where to dig only by hand.  The
device is in two pieces, one of which couples RF onto a cable by induction
(from up to several feet away); the other piece is a receiver which detects
the re-radiation from the cable up to several feet away.  The transmit unit
and the receive unit need to be separated about fifty feet apart or more for
this to work.  Otherwise, you will get direct coupling through the air and
not via the conductor you're tracking.  The receiver sensitivity was
adjustable on the one I used.

I rented our unit from a surveyors' supply house.  Rent, try, buy.  good
luck.

Hello, and one more (and final) time: Electric and magnetic fields by themselves don't propagate, only electromagnetic fields (EM) can transport energy over vast distances. A transmitting antenna has LOCAL (near) electric and magnetic fields but what propagates (i.e. what a receiving antenna sees as the far-field) is an EM field. A receiving antenna has an "effective area" that captures energy in the incident EM wave; what isn't dissipated in the load at the receiving antenna terminals is reflected (scattered) by the antenna (after allowing for any dissipative/ohmic losses in the antenna structure).

As economics professor Peter Morici would say "It isn't all that complicated." (But the devil's in the details). Sincerely and 73s from N4GGO,

What a small shielded loop responds to should be easy to demonstrate. We kn=
ow that a florescent light bulb responds mainly to the electric field becau=
se it gets brighter as one moves it from the feedpoint to the top of a mobi=
le antenna. The standing wave voltage loop is at the top of a resonant mobi=
le antenna. The standing wave current loop is at the feedpoint of a resonan=
t mobile antenna.

So simply take the small shielded loop and see where it responds the best u=
p and down a mobile antenna. If some people are correct about it responding=
 mainly to the magnetic field, the measured field strength will be highest =
at the base of the mobile antenna where the standing wave current is the hi=
ghest.

Hello, and one has to make the distinction of whether the receiving loop is in the near or far field with respect to the source of the incident energy. A quick test is to note whether shorting or open-circuiting the terminals of the loop (or any receiving antenna for that matter) has any effect on the current flowing into the terminals of the source (transmitting) antenna. If there's no effect then the receiving antenna is most likely decoupled inductively (magnetically) and capacitively (electrically) from the transmitting antenna. What is seen as available power at the receiving antenna in that case is due to its interception of a propagating EM field. The fact that the orientation of an axis of the antenna aligns with the E or H component of an incident EM field is just a result of the applicable electrophysics. Sincerely,

There is the knowledge amongst most hams who work low bands that a loop antenna has much less noise than a dipole at the same height. This is especially true in a suburban area. The ability to hear the other station in a qso is profoundly effected by the noise level heard in your receiver.

I just had a very long conversation with a fellow ham who has been experimenting with antennas for over 50 years. He has lived in the same rural place all that time. He has no homes anywhere near his own. His noise level in his receiver is not much reduced by using a horizontal loop. He does like loops and his most used antenna is a 160 meter quad loop vertically mounted with its top at 200 feet.

Anyway I was trying to understand why my loop antenna reduced my noise level in my receiver by so many S units. After at least an hour of conversation we got to the fact that I had built a portable loop antenna for 2 meters as a direction finder. He pointed out how sharp the null was when this antenna was pointed (edge on) toward the source station. He then said to take this antenna and then turn it horizontal and see if I could hear anything. Voila. Nothing at all was heard. I finally understood the reason for the remarkable noise immunity of the loop antenna. The loop simply nulls all noise and signals from its edge on plane. So, any signals from nearby homes, power lines, and industry are received by me at this very low angle of radiation. They are nulled out. I receive only high angle radiation. This is also true of transmitted signal and thus the large amount of gain it has as an NVIS antenna. This is not magic, just physics.

My 75 meter transmitted signal in the day stops at about a 300 mile radius. This is fine for me. It may not be fine for others. I regularly talk to California from Michigan during the night on 75. This same antenna works DX on 40. I do not understand why at this point. I have received an S9 signal report from Barcelona Spain on 40. It also works other bands, but its performance on 40 meters is better than any other band. In any case my interest in this subject was piqued when someone here said that it was just mythology that loop antennas had any more noise immunity than a dipole. I knew this was not true from my own experience but wanted to understand why. '

So in finishing up, a horizontal loop probably offers little noise immunity when operated in the countryside where you have no nearby sources of interference. It offers a lot of noise suppression when operated in the city or suburban areas.

Michael

One thing must be mentioned:
The noise cancelling effect of loops is best when the loop is small
compared to the wavelength.
As the loop gets greater, the effect reduces to nil.

Imagine an electric field
```
------------------------------------>
------------------------------------>
------------------------------------>
------------------------------------>
------------------------------------>
```

now imagine the loop, I can only draw a square
in fixed pitch font:

```
>>>>>>>>>>>>>>>>  upper conductor
|              |
|              |
|              |
|              |
|              |
<<<<<<<<<<<<<<<< lower conductor
```

It is immediately clear that the upper part
signal will be cancelled by the lower part signal
and the same applies to the left and right parts
of the loop and of course this applies also to
a circular loop in the electric field, while the signal
from a magnetic field perpendicular to the computer screen
where you are watching this, ahemm..., the magnetically
induced signal adds up around the whole circumference
of the loop.

I hope the SECRET of the loop is finally lifted

and everybody says: yeah, I knew it anyway,
you don't have to tell me, it is so simple.

Large loops do not cancel out the electric signal completely
as the el. field is not in phase on all sides of the loop
and therefore such a loop should be shielded.
When acting at 20 meters, a meter diameter loop is small
compared to the wavelength, at 150 MHz a 40cm diam. loop
is no longer small compared to the wavelength.
This is where shielding helps to minimize electrical
field pickup.

w.

Do you want to claim that the kind of waves radiated from a transmitter
antenna varies depending on the type of antenna?

So that a dipole antenna produces another kind of wave than a monopole
antenna?

It should then be possible to determine at a distance what kind of
antenna was used to transmit the wave.   Can you describe an experiment
to do this determination?

Faraday wrote in 1846 that to have the polarized waves you must use the two
or more sources.

To have the linear polarization we are using the dipole.
To have the circular polarization we are using the two dipoles.

The above is easy to "determine at a distance what kind of antenna was used
to transmit the wave."

But is the another phenomenon. The Luxembourg effect.
The dipole radiate the doubled frequency.

Once again our resident babbling idiot takes a snippet of something from
Wiki totally out of context, and misinterprets it.

It has been explained to you several times that any electron emmission
from the ends of an antenna is an abnormal situation, is NOT required
for antenna operation, and is an independant phenomena of normal antenna
operation.

It has also been explained to you several times that there are types
of antennas where this never happens.

Yet you keep babbling on like the totally ignorant idiot you are.

Just about everything you said here is total, babbling, nonsense.

You are an idiot and will always be an idiot.

Ah yes - the famous "is it a dipole or is it a dipole?" test. Of course, it wouldn't discriminate between a dipole and a yagi (staggered or phased?)

Luxembourg effect? Harmonics?

My guess is that the quote from Wiki relates to vacuum tubes. Ah yes, it does. Shall we put the farmer's barn into a large vacuum?

As I said ...

Did you read the final comment - "I am afraid that Peter Stuart has been misled. There is not the slightest chance of "tapping in" to the power being

radiated even from the highest power stations". That came from someone who
ran high power transmitters.

How much power input or output does a transmitter have to have in order
for it to be a "powerful" transmitter? I have a 400W transmitter around six
miles away and a 200kW transmitter around 50 miles away. Which one's signal
will be the stronger at my house?

How accurate are science based reports in the Telegraph?

Nothing invented in the 20th century? Nuclear weapons, the Internet, String Theory? Ptolemy chose the earth centric model. Copernicus disproved it and developed the sun centric model. Galileo was somewhat unpopular with the church for supporting the earth centric model.

And after 166 have passed, we know that is not correct.

> To have the linear polarization we are using the dipole.
> To have the circular polarization we are using the two dipoles.

To have circular polarization, we also use helical antennas, something
that didn't exist 166 years ago.

We also have various types of loop, dielectric and waveguide based antennas,
such as the slot antenna, that did not exist 166 years ago.

> The above is easy to "determine at a distance what kind of antenna was used

No, it is not, in fact it is impossible to do.

> But is the another phenomenon. The Luxembourg effect.
> The dipole radiate the doubled frequency.

The Luxemburg-Gorky effect, which is the real name, has nothing to do
with antennas.

This is just more of your babbling idiocy.

I share your skepticism, Ian, and I'd like to take it a step further.

There is real math (imagine that!) to address the notion of "stealing power from a nearby transmitter." Free-space attenuation is given by the formula 20 log Rf + 37dB, where R is the range in Nautical Miles and f is the frequency in MHz.

True, a close-in VLF transmitter gives good coupling and actually will light an unconnected fluorescent tube. However, these stations are quite rare and nobody moves near them to "steal power," since they are built in large open areas with fences and guards. Need backup plan.

Next best bet: Get within 500 feet of a 50KW AM station, say KFI, AM-640 or KBOI, AM-670. Per the formula, the coupling loss will be about 13 dB, making 2500 watts of power available to you at that location. However, to realize that power, you need an antenna with near unity gain at that frequency. Any guesses as to how much they cost? Try $Millions. (It's called a 600-foot tower.) Much better to call your local utility and tell them how much you appreciate their service. Resolve to be more realistic about power-robbing schemes.

COMING NEXT ON THE POWER ROBBER CHANNEL: Tap into your neighbor's garden lights -- it's easy!

73,
"Sal"

Hello Sal. Thank you very much for the maths and the workings. Stories of "getting useable power from a transmitter" are always hard to track to an accurate source. The nearst I've gotten is a friend who knew of a cottage with a 33kV power line passing overhead. Seems that some turns of wire were fitted under the cottage's eaves and some useful power was obtained. Transfoemer action, I assume.
I've read science fiction stories form the 1930s where "broadcast power" was in general use. One story had all users switch off their powere receivers so that the authorities could D/F a wanted person by measuring the strength of the power field. Ah - unfettered imagination though induction does work when the power source and appliance are close together.

73, Ian.

The commercial power in my neighborhood has an asymmetric waveform. Some of
us have been saving the extra electrons on one-half-cycle. We had a power
outage in October of last year and what we're saving now will be used if we
ever suffer another outage.

The extra electrons flow into the ground. Like in your radios.

Fundamentals of radio.

>Ptolemy chose the earth centric model.

Today astronomers do the same. The Sun is too hot to make the measurements
from it.

>Copernicus disproved it and developed the sun centric model. Galileo was
>somewhat unpopular with the church for supporting the earth centric model.

Copernicus and Galileo were trying to change the teaching program.

The same is now.

It is time to replace the EM by Heaviside with Ampere electrodynamics.

Harmonics are in string, plate, piano box etc.

Pendelum and LC circuit have the one frequency only.

LW from the dipole mast were (and are) received on MW receivers at exactly
doubled frequency.

Yup. Harmonics. The Luxembourg effect was cross-modulation. I'd completely forgotten about it.

Was it a dipole or was it a dipole?

Regards, Ian

I beg to differ and hair split. The free space attenuation formula works nicely at a distance of about 1 wavelength or more away from the antenna. However, at the broadcast band wavelength of about 300 meters (about 1000ft), any attempt to steal power will probably require near field calculations, or perhaps just transformer action.
<http://en.wikipedia.org/wiki/Near_and_far_field>

>Next best bet: Get within 500 feet of a 50KW AM station, say KFI, AM-640 or
>KBOI, AM-670.

RF safety exposure limits at 500ft for a 50KW AM station and 0dBi antenna gain, yields about 1.5 mw/cm2. The safe limit is 100mw/cm2.
<http://kb9mwr.dyndns.org/n9zia/rfsafety.main.cgi>
Therefore, it is safe to approach the antenna without fear of having your brain morph into Mr. Bialek. At about 60ft is becomes officially unsafe.

>Per the formula, the coupling loss will be about 13 dB,

Technology to the rescue. Once upon a time in the 1960's, I lived in Smog Angeles and worked part time next to an AM station. Surrounding the antenna was the requisite chain link security fence, which had several gaps in the fence for access gates. If one of the gates was left open, forming a 1 turn coil, I could draw a small arc across the gap with a clip lead. I wanted to fake an electrocution by bridging a gate with both arms, but chickened out. When the station personnel found out what us juvenile delinquents were doing, they promptly buried a wire across each gate to short out the gaps, and changed the locks on the gates.

Incidentally, locating the Gertsch/Singer (manufacturer of communications service monitors) factory next to an AM broadcast station (I forgot the call sign) in LA was not a great idea.

>COMING NEXT ON THE POWER ROBBER CHANNEL: Tap into your neighbor's garden
>lights -- it's easy!

Yech... The next revolution in home alternative energy will be the nuclear powered underground water heater and the solar powered steam plant. Dispose of hot nuclear waste and run your water heater at the

same time. If you do the math, solar steam power is cheaper and more
efficient than solar cells.

Somewhat more seriously, I've been reading about nantennas for solar
power. With 85% theoretical efficiency, it sure looks promising.
<http://en.wikipedia.org/wiki/Nantenna>
<http://www.inl.gov/pdfs/nantenna.pdf>
Maybe there's a place for RF engineers in alternative energy. All I
need to do is build a 3,000GHz antenna farm and find a diode that
works at that frequency.

It wasn't called physics back then.  It was "natural philosophy".
<http://en.wikipedia.org/wiki/Natural_philosophy>

Back then, to give one a "physic" was to administer a cathartic and
force regurgitation:
<http://en.wiktionary.org/wiki/physic>
That's fairly close to what I feel when reading your claims and
distortions.

You don't have the slightest clue what the term "field electron emission"
means and keep using it in the most inappropriate of situations.

There can't actually be a real person this blazingly, blindingly stupid.

Someone this stupid would be incapable of feeding and clothing himself.

Oh dear - no. Astronomers to-day know that the earth orbits around the sun.
It is incorrect to say that "the sun is too hot to make the measurements".
Scientists make plenty of observations of the sun (sunspots, CME and so on).

Regards, Ian.

The principle of nantenas is the same as the crystal radio.
The size of the antenna must be below 1/2 WL.

For RF each diode is O.K.

The question is if the electrons flow into the ground.

Do you know the answer?

It is an explanation.
The Luxembourg effect WAS the receiving of LW from Luxembourg mast on the MW
receivers tuned to the doubled frequency..

All measurements were, are, and will be done from the Earth.

"Ptolemy chose the earth centric model" means that all measurements must be
done from the Earth.
All astronomers before Ptolemy (and he) known that the planets orbit the
Sun.

Oops - no. Ptolemy's earth centric model meant that the sun and other
planets orbited the sun.

Ah - so Wikipedia is incorrect. It reads " ...  Luxemburg-Gorky effect is a
phenomenon of cross modulation between two radio waves ... ".

The effect has nothing what so ever to do with antennas.

You are an idiot.

This idiot is so blindingly stupid he doesn't know we now have space craft
and automated measuring devices.

One wonders if he gets around his village on horseback.

Nah, he's too stupid to be able to ride something as smart as a horse.

Maybe a goat cart if someone else hooks up the goat for him and steers.

Please read the PDF I included. The length of the dipole can be any multiple of 1/2 wavelength. It can also be a loop antenna. What's critical is the spacing between the antenna and the underlying ground plane, which form a resonant cavity at optical frequencies.

>For RF each diode is O.K.

Please read the Wikipedia article:

> The large loss in power is a result of the junction
> capacitance (also known as parasitic capacitance) found
> in p-n junction diodes and Schottky diodes, which can
> only operate effectively at frequencies less than 5 THz.[3]
> The ideal wavelengths of 0.4-1.6 um correspond to
> frequencies of approximately 190-750 THz, which is much
> larger than the capabilities of typical diodes. etc...

This isn't going to work with ordinary diodes.

>The question is if the electrons flow into the ground.

Nope. The question is whether there are any electrons involved. There are none.

>Do you know the answer?

Yes... I know everything. If you unable to form a suitable opinion, I would be happy to supply one for you.

Everyone constantly repeating that there are no electrons falling to the ground or spewn into the air doesn't seem to have much of an effect on you. You are also apparently incapable of answering my question (multiple times). I see no indication that you have read, much less understand, any of the references and explanations supplied for your benefit. You are therefore hopeless and a waste of time.

Dunno.. You are being pretty hard on the chickens.. :/
Heck, I saw chickens and ducks playing the piano at the I.Q.
Zoo in Hot Springs AR several years ago. :|

Is the cross modulation if the LW are from the monopole antenna?

"The simplest crystal radio receiver, employing an antenna and a demodulating diode (rectifier), is actually a rectenna - although it discards the DC component before sending the signal to the earphones. People living near strong radio transmitters would occasionally discover that with a long receiving antenna, they could get enough electric power to light a light bulb"

Where the DC component is discard?
What is the DC component made of?

"The electrical grid, which is normally three-phase AC, can be severely disrupted by the presence of a large DC bias. This is caused by strong solar flares hitting the Earth's atmosphere,(Even pipelines, such as the mostly above-groundAlaska Pipeline, are prone to this, and must be tied to electrical ground".

Now you are only one. Two days ago Jimp wrote:

"It has been explained to you several times that any electron emmission from the ends of an antenna is an abnormal situation, is NOT required for antenna operation, and is an independant phenomena of normal antenna operation."

So we have done the first step: "electrons falling to the ground or spewn into the air" are the abnormal situations".

The next step will be "L. Lorenz is right".

The electrical grid has nothing to do with antennas and the structures being discussed are usually miles long in size.

There are no antennas miles long in size.

No, we do not.

Even in a solar flare there are no "electrons falling to the ground or
spewn into the air".

Solar flare effects at ground level are magnetic effects.

And like many of your other ancient references, it was wrong.

There is no relationship to the frequencies.

Cross modulation has absolutely nothing to do with antennas.

It is an effect caused by a perturbed region of the ionosphere far from
the antennas.

You are a babbling idiot.

"In 1933, Radio Luxembourg opened a 200 kW long wave transmitter,
broadcasting in English from the Grand Duchy in the afternoons and
evenings."
From: http://frequencyfinder.org.uk/trans_hist1.html

It was a dipole mast. The same was in Warsaw . The same effect was observed
(the LW were received on radio set as MW).
Now is a 1/4 WL mast and no the effect.
S*

And the LW station caused cross modulation of a MW station, resulting
in the LW station being heard at the same time as the MW station on
the MW station frequency.

> It was a dipole mast. The same was in Warsaw . The same effect was observed
> (the LW were received on radio set as MW).
> Now is a 1/4 WL mast and no the effect.

Incoherent, meaningles babble.

The Luxembourg effect has nothing to do with antennas and happens in the
ionosphere.

>Solar flare effects at ground level are magnetic effects.

Thanks. There's an all too common misconception that the engergetic charged particles produced by solar flares, solar storms, solar wind, CME's, etc somehow land on the power lines, which then appears as a DC voltage on the lines. That's not how it works at ground level. This explains it better than I could:

I can almost guarantee our babbling Polish idiot believes that solar
produced particles make it through the atmosphere, which they do not.

All that energetic crap from space winds up being trapped by the air in the
upper atmosphere, ionizing the air from about 85 km to 600 km in altitude,
which is why the ionosphere exists.

It occurs to me I should probably define the term "energetic crap from space".

What is meant is any particle or EMR with sufficient energy to knock an electron off of an atom.

For EMR, that starts in the UV region, which is the primary source for the ionosphere under normal conditions.

During solar flares, there are LOTS of high energy particles being ejected by the Sun of sufficient energy which add to the mix.

For an off topic amusement:

I did a search for our babbling Polish friend and the first thing I found was a message posted to a Polish medical list where he claims all cancer is a fungus and should be treated with Epsom salts.

It appears his idiocy is boundless.

Not me:
I have informed that somebody wrote:
"" I read Dr Simoncini's (oncologist) site at http://www.curenaturalicancro.com/ that basal cell is a candida fungus, in fact he claims ALL cancer is a fungus, and he recommended tincture of iodine 2x per day onto the basal cell. I tried that and had a major clearing but could not get the entire thing removed plus an iodine stain is not exactly wonderful on your head! I then pursued the candida angle and read that magnesium sulphate (Epsom Salts) saturated solution in water is deadly to almost any fungus/yeast. Well, after 1 week of applying this it has sorted out my basal cell and removed it completely. That stuff is dirt cheap and works."

Before I have read that J. Schneider used the Epsom salt to cancer cure.

Do you know same examples of using the Epsom salt?

In the teaching program the stationary electron create the electric field.
The same electron during travel create the magnetic field.

So should be obvious for you that if you detect the magnetic field it means
that close to you is the electron flow.
No magnetic field without the electron flow.

In physics "magnetic effects" = electron flow.

If you detect the magnetic field it means that the electrons "land on the
power lines, which then appears as a DC  voltage on the lines."

Faraday and Marconi did not go to schools.
Would be better the same for you.

Is about the sodium bicarbonate. Epsom salt is a magnesium sulfate:

Somebody wrote:
"I then pursued the candida angle and read that
magnesium sulphate (Epsom Salts) saturated solution in water is deadly to
almost any fungus/yeast. Well, after 1 week of applying this it has sorted
out my basal cell and removed it completely. That stuff is dirt cheap and
works."

Before I have read that J. Schneider used the Epsom salt to cancer cure.

The Solenoid is a magnet.
Probably in the permanent magnet are many solenoids (Ampere).

In schools are fields.
In reality are the electrons.
The Suns is the bigger transmitter of the electron waves.

If you develop cancer, PLEASE refuse modern medical treatment and go with
epsom salts.

True.  However, to be of any future use, they must be captured before this
can happen.  I'm keeping mine on a shelf in the back pantry.  The first box
is nearly full.

A box is not the best condenser.
You should use the Leyden jar.

J. Schnieder (GRAB SADDLE) did it. He was using the saturated solution of
Epsom salt +Vit C.
The National Center Institute Found that " it killed melanoma, renal, brain,
ovarian, leukemia, colon, CNS and 2 types of lung cancer".

I had the melanoma and "go with  epsom salts." But I was sure that it is a
"modern medical treatment".
Of course the cancer disappeared after two weeks without a scar.

John Schneider discovered the cancer cure and Grab Saddle.

Sorry for the delay, work kicked me for a while.

I finally got back to checking and the noise is louder and when unhooking the tuner (which is attached to the dipole) the noice immediately goes away. Yesterday was about S9 or S10 of constant noice coming over all the bands on the HF.

Is there any good Intermod filter for older style solid state rigs? There must be a cell phone tower or plazma tvs all over my neighborhood. Only way if that is the case to eliminate this is a intermodulation filter of some type on my end.

Any good comments I am appreciative, cheap comments welcome as well.

73s

Does "unhooking the tuner" mean that you've unplugged the antenna lead from the plasma TV, or that you turned off the plasma TV? If the RFI is really coming from the antenna connection of the TV, a simple 54MHz high pass filter should be sufficient to reduce the RF emissions at HF frequencies to tolerable levels. However, I think turning off the TV would be better.

>Yesterday was about S9 or S10 of constant noice coming over all the bands on
>the HF.

I was playing with a Heathkit GC-1000 WWV clock a few nights ago. Reception was horrible and there seemed to be a rather high noise level. I turned off everything I could think might be the culprit and the noise was still there. I gave up for the evening. When I turned

off the room lights, the noise went away. One LED lamp turned out to be the culprit:
<http://www.homedepot.com/webapp/wcs/stores/servlet/ProductDisplay?productId=203088292>
I have 3 of these running, but only one of them generates RFI.

>Is there any good Intermod filter for older style solid state rigs?

There's no such thing as an "intermod filter". Intermod is the result of mixing two signals. That's not what's happening in your case. It's just plain old conducted or radiated RFI and EMI.

>There
>must be a cell phone tower

Cell towers do not have anything to do with your noise problem. Cell towers operate at 700MHz and up. Your HF activities are 2-30MHz. However, one major (local) source of RFI/EMI are line synced solar inverters. Most are fairly clean, but some of the older inverters required line filters, which tended to be an added option rather than a requirement. If the noise level follows the sun, look for solar panels on the rooftops.

>or plazma tvs all over my neighborhood.

Yep. Incidentally, we had a little transmitter hunt trying to find what seemed like an obvious plasma TV noise source. However, when we turned off the plasma TV, the noise was still there. It was eventually traced to a nearby "Ionic Breeze Air Purifier" with a very noisy hi-v power supply. It was exchanged for another under warranty, which was even noisier.

>Only way
>if that is the case to eliminate this is a intermodulation filter of some
>type on my end.

You can't "eliminate" EMI/RFI on your operating frequency with any type of filter. You have to eliminate it at the source. You can make improvements if you can determine the path from the alleged source to your HF rig. If it's radiated, shielding at the source, moving things around, and adjusting antennas. If it's conducted, power line filters, at both ends, will help. Meanwhile, make friends with the neighbors, convince them to "upgrade" to LED TV's, or adjust your operating hours to when the plasma TV's tend to be off.

```

Well, might as well go further off topic. I'll make it quick and painless.

In about 2006, I discovered that I had prostate cancer. I had some time, so I elected watchful waiting, while I shopped around for alternatives to conventional cancer treatments. I settled on 3 rather popular treatments and tried them all with religious adherence to their recommended procedures and strictures. Nothing worked, and my PSA score continued to climb:
<http://802.11junk.com/jeffl/crud/psa.jpg>
(The big peak in 2007 was from the effects of a kidney stone.) As I approached meltdown, I finally elected to have my prostate surgically removed. A year later, I had to go through radiation treatment to clean up the mess because I had waited a bit too long.

During this exercise, I learned a few things about alternative medicine and cancer.
1. There are plenty of people that do absolutely nothing and have the cancer miraculously disappear. It's more common than I suspected. I know two such people.
2. History is written by the survivors. The failures of any alternative procedure is unlikely to write a report indicating that they had died from the procedure. Those that survived, and where the alternative treatment failed, are unlikely to report the failure. Of course, the proponents of the alternative treatment are unlikely to mention failures. The result is the overwhelming number of user comments on alternative treatment web sites are positive.
3. There are huge number of scams and disreputable medical schemes on the internet. There are also credible looking research reports, which offer conclusions not substantiated by any data. Some reports go so far as to be self-contradictory. I found one that couldn't even get the arithmetic correct.
4. The way to separate the scams from real research is to determine if the author has a financial interest in the procedure. If they're selling a book, potion, drug, procedure, or have a political agenda, then they should be ignored. What's left are usually government and university financed studies.
5. Alternative medicine certainly has its benefits. In general, it's a great way to clean up a bad lifestyle. Living on junk food, not getting enough exercise, and high stress all have their effects. However, the price of alternative medicine might be delaying conventional treatment, which often has fatal results. That's roughly what happened to Steve Jobs, who delayed pancreatic cancer surgery a bit too long.

Feel free to try Mr Bialek's recommended treatments. However, have your exit strategy ready in case they fail.

It should be with the low leakage. The Leyden jar has a thick insulation.
And,

"Any type of capacitor may develop excessive leakage if the capacitor is subjected to excessive applied voltage or high-voltage spikes."

.It was known in Marconi time:
"It is now perfectly well known that a condenser, if large enough, does not prevent the passage of high frequency oscillations, and therefore in these cases
the earth is for all practical purposes connected to the antennae." (Marconi 1909).

In reality the real condenser conducts (electrons are flowing) the DC but do not AC.
In the teaching program is opposite.

J. Schneider published his results in 2006 after 15 years of experiments.
The National Cancer Institute confirmed it.
Your "alternatives" were the old ones.

But J. Schneider wrote:
"I have no idea if my body was unique in its response to this agent
(saturated solution of Epsom salt + Vit C).
It is obvious that that much more laboratory and clinic testing is necessary
before anyone could recomended this agent to anyone else for their use".

Now I know that my body is also unique.

I agree with you in 100%.

But the J. Schneider cancer cure is not an alternative.
It is tested in the National Institutions.

>

Not my but John Schneider who discovered the cancer cure and Grab Saddle.

What an utter idiot.

Who wants to try to explain to this babbling idiot that the impedance of
a capacitor is 1 / (2 X pi X f X C) which means if f is zero (DC) the
impedance is infinite and there is no conduction (in an ideal capacitor).

The NCI doesn't confirm anything or do any research or experiments. They're a government organization that catalogs, organizes, and reports on other peoples and organizations research. The only place where the NCI funds reports are for maintaining the statistical database and running regular surveys of best practices and research trends. I believe (not sure) that they also insist on peer reviewed research.

Searching cancer.gov and scholar.google.com for "J. Schneider epsom salt", I find nothing. URL please? Any double blind clinical trials?

The Leyden jar is small. Holds only a few dozen coulombs. Shoebox holds
hundreds and I already have plenty of shoeboxes, plus friends who have
shoeboxes. The lid needs to be taped down or the mutual repulsion of the
electrons will push it up and off.

I'll take that into account the next time I'm connecting a bleeder across a
power supply output. Now that I know a capacitor will work ...

> Well, might as well go further off topic. I'll make it quick and painless.
>
> In about 2006, I discovered that I had prostate cancer.

I got the bad news in 2005, after several years of a rising and falling PSA and one negative biopsy in July of 2004. I had been watching news for prostate cancer, so I knew what the treatments were, who was using them and what the success rates were. (Now, seven years "down the pike," things may be different; my perspective reflects best practices as of my diagnosis.)

I opted for surgery. When my urologist asked what I wanted to do, I already knew. I said, "I want it out with the da Vinci robot."

He said, "We have that."

I said, "I know." I had read that my provider had gotten the first robot in San Diego earlier that year. I was referred to the surgeon who bought the robot and was accepted as a candidate. Six weeks later, done. PSA undetectable ever since; he got it all. Officially "cured" in another fifteen months, eight years post-op. I was probably lucky in many regards. The urologist was aggressive and he admitted it.

He said, "I do more biopsies than anybody I know. It means I catch more cancers." (The biopsy has some slight pain associted with it but it's only mildly uncomfortable. I'd take a dozen in preference to having a tooth capped, for example."

My provider, having just gotten the robot, didn't require me to ask them to pay for me to go off-network. My surgeon was the Chief of Surgery who had moved up through Urology, so he had done thousands of prostatectomies. I go back to see him every year. He's since been promoted to Chief of Staff but he still works Urology. Great guy.

>

Some things:

CHARACTERIZATION: See if the noise is truly on all the bands. Check every band for which you have a suitable antenna. Tell us what bands are bad and how bad. Is the problem the same at 2:00 AM as at 8:00 PM? Do you have access to a spectrum analyzer?

LOCALIZATION: Get yourself a lot of coaxial cable, perhaps 100 feet and relocate a portable antenna to places around outside your shack while another ham calls out the S-meter reading every time you stop someplace and ask for it. You don't have to have a particularly good match so I'd suggest you DON'T need ground radials -- just a hamstick on the end of the cable. Don't hold onto it while your buddy takes the reading; hold it upright with a plastic or wooden stick a few feet long. Consider buying or borrowing a portable radio that covers the frequencies affected.

ISOLATION: If you can localize the source, begin powering down. You may be able to switch off breakers, pending other persons in the house having their TV go off, or the kitchen go dark at dinnertime, etc. Run your rig off a battery so you can power down your entire shack. The source could be in a neighbor's house.

WILD GUESS: Does the tuner have any active circuitry in it? It would be a real b*tch if the noise were being generated inside the tuner. When you mentioned "unhooking the tuner," you didn't say which side you were unhooking.

SNEAK FACTOR (1): A battery-backed-up device, like a smoke detector, CO detector or burglar alarm could be the problem, but I doubt it.

SNEAK FACTOR (2):   If you have more than one problem, you may not know about Number 2 until after you fix Number 1.

Good luck. I worked interference problems for the Navy and sometimes you need luck to back up your skill.

I accumulate my electrons in a RubberMade Packer box all year. The box is
big and well insulated
```

and also holds my Field Day radio and antennas. In June, I take it to the FD site all charged up
and ready for Qs.

So far the best light (warm white), best efficiency and relatively low
noise seems to be from Philips LED bulbs.  The ones that have the orange
top are the best.  Nothing else comes close.  In Minnesota I think there
is a deal going on with Home Depot and the power company because the 60W
Philips bulbs that are normally $40 online everywhere have been $15 at
Home Depot (here) for months.

They are much better than any other LED Edison style bulb I have
```

purchased, and I've bought quite a few trying to figure out what's good.

The best price/performance is at the 60W level where the $15 bulb produces 810 lumens for 12W with color rendering at something like 80. The better version of the bulb does 1100 lumens (or so, can't remember the number exactly) for only 10W and has about a 99 color rendering rating. And is $50, only available online. I'd love having that one, but the math doesn't work out even if I have it for 30 years. I'll wait for the price to go down.

I lied.  If the noise source is coherent, you can get rid of the trash
with a noise canceller:

>
> Searching cancer.gov and scholar.google.com for "J. Schneider epsom salt", I find nothing. URL please? Any double blind clinical trials?

I have come accros Epsom salt in 2007.
The most interesting was Schneider's "CANCER CURE PAGE".
It starts it words: "I mix my cancer cure as i explain in item #4 on this "CANCER CURE PAGE"
I have the printout but without URL.
Two years ago I have lost the all what was on my PC.

Schneider did not write why the Epsom salt cure cancers. So it was interesting for me the two steatments:
"ALL cancer is a funge" and "that
magnesium sulphate (Epsom Salts) saturated solution in water is deadly to almost any fungus/yeast. Well, after 1 week of applying this it has sorted out my basal cell and removed it completely. That stuff is dirt cheap and works."

It is known since XVI century that Epsom salt cures all skin problems.

Todey I found:
"
Sea Salt Water Drink -
Dr. F. Batmanghelidj MD believes that salt is vital for theprevention and treatment of the cancer. Cancer cells - he explains- cannotleave in an oxygenated environment. When the body is well hydrated and saltexpends the volume of blood circulation to reach all parts of the body, theoxygen and active immune cells in the blood reach the cancerous tissue anddestroy it. All refined salt should be discarded as its harmful to the body"

Unrefined sea salt has many Mg and S ions.

Do you use the unrafined sea salt?

You and teachers live in the ideal world where are the ideal capacitors.

Leyden jar has insulator made of glass.
It is possible to make it with insulator "made" of the air.

What will be leakage in such case?
S*

```

After an interesting weekend working DX on 17 meters using a homebrew 5 band vertical antenna, I had a thought....... how much better would it be to have a 2 or 3 element yagi on 17 and maybe 12 as well.

So here is the plan, either open sleeve feed the 17 and 12 meter driven elements by close coupling it to the trapped driven element of my old Wilson SY 2 tribander that is at 50 feet above the ground. Or build a open sleeve fed 17/12 meter 2 el yagi and position it on the same boom as the tribander and run a separate feeder to the 17 meter driven element thus allowing greater separation of the new elements from the original tribander elements.

I have looked around for generic trapped tribander models (MMANT-GAL) but have found nothing. I am new to antenna modeling, but have read that trapped triband yagis are difficult to model.

Is there any experience on the forum with this type of modification of an existing tribander and if so what were the results like.

I have a fair stock of aluminium to make the new elements from, so the project will cost me not much than the time I invest in it.

I am not interested in buying an all singing 5 band optibeam or StepIr antenna, I would like to increase my performance on 17 and possibly 12 meters without degrading my performance on 20, 15 and 10 too much. I also suffer from short arms and deep pocket syndrome.

Your thoughts (and sensible responses) are appreciated.

Mike VK3XL

Errr ... if your computer used capacitors with air dielectric then I doubt
we'd hear from you again.

If it helps you, capacitors pass AC and block DC.

Regards, Ian.

They're about $40 at Home Despot. I was there yesterday to check. I
would probably have bought them except that the cheapo 8 watt Ecosmart
LED lights were on sale for $10/ea. I don't know if you caught my
comment, but I have 3 of them (now 4) but only one generates RFI. I
was going to exchange it for another, but forgot to bring it to the
store. Maybe next time.

>The best price/performance is at the 60W level where the $15 bulb
>produces 810 lumens for 12W with color rendering at something like 80.
>The better version of the bulb does 1100 lumens (or so, can't remember
>the number exactly) for only 10W and has about a 99 color rendering
>rating. And is $50, only available online. I'd love having that one,
>but the math doesn't work out even if I have it for 30 years. I'll wait
>for the price to go down.

By comparison, the 8 watt EcoSmart 40w bulb produces and insipid 430
lumens and a 3000K color temperature. Like all the blue+yellow=white
bulbs, they tend to favor the yellow. My eyes can be easily fooled,
but my camera and spectroscope shows the obvious:
<http://802.11junk.com/jeffl/crud/EcoSmart%209%20Watt%20LED.jpg>
Argh... I can't find the spectra photo.   These look like fun:

I live in the real world and it is trivial to verify that the impedance
of a capacitor is 1 / (2 X pi X f X C).

As usual, you are totally confused.

Leakage and impedance are two separate things, idiot.

Each insulator is a weak conductor.
At DC and pulse current electrons are flowing through the insulator
(leakage).
At AC not.
```

At AC the charging/discharging take place. The electrons flow into plate and
come back.

Charging current and discharging current do not pass or by-pas the
capacitors.

An insulator is ... an insulator. No leakage. If an insulator is not
insulating then you'd better handle your mains leads with care.

ttfn, Ian.

I used to keep all of my spare electrons in my hair. I would just use a
comb in dry weather to collect them. However, since going bald I have no
more spare electrons..sigh....

Michael

Last time I looked Poland had coastline on the Baltic Sea.

Take a train/bus/goat cart to the sea along with a big bottle and get
all you want.

>> salt", I find nothing. URL please? Any double blind clinical trials?

>I have come accros Epsom salt in 2007.

URL please. If you cannot find a suitable published and peer reviewed research report or clinical trial results, I would consider your recycled medical advice to be in the same class as your physics. While there is a tiny possibility that an obscure scientist may have discovered or rediscovered something profound, the odds are against this happening. More likely, he's yet another medical fraud.

>The most interesting was Schneider's "CANCER CURE PAGE".

URL please. Google didn't find anything. I'm beginning to wonder if this J. Schneider even exists. All I can find with Google are your posting proclaiming his miraculous cancer cure.

>Do you use the unrafined sea salt?

No. I also have cardiac issues and make an effort to reduce my sodium
salt intake. I rarely add salt to anything (except popcorn).
<http://802.11junk.com/jeffl/crud/salt.jpg>
I prefer to get my beta particles from Potassium salt substitute.

I have a new capacitor design that uses clam chowder as the dielectric.
Interested?

I WILL BUY YOUR BROKEN/TRASHED ICOM H.F. RADIO

Hi,

I want to get back on the air by seeing if I can fix a trashed or
non-working Icom h.f. radio.

Has to be cheap.

Thank you.

Summary: Recruitment announcement for ham-radio-related FAQ articles
Keywords: FAQ, Intro, amateur, ham, radio, recruit, recruitment

Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/recruitment
Revision: 1.2 2009/11/25 14:41:01
Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

```
One significant omission, requiring immediate updates, for this article       |
is that it does not mention newer amateur radio newsgroups created since      |
it was written, including:                                                    |

 rec.radio.amateur.antenna                                                    |
 rec.radio.amateur.boatanchors                                                |
 rec.radio.amateur.dx                                                         |
 rec.radio.amateur.equipment                                                  |
 rec.radio.amateur.homebrew                                                   |
 rec.radio.amateur.moderated                                                  |
 rec.radio.amateur.space                                                      |
```

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

The Baltic Sea is like a lake (0.3% of salt).
In oceans is 4%.

Hello folks.
I'm not sure about "Hopefully not off topic" but I have a niggling feeling
that cancer treatments, Epsom salts (even though I used to visit Epsom) and
suchlike may not be appropriate for rec.radio.amateur.antenna
so perhaps Szczepan should find a more appropriate medicine, homeopathy or
cancer newsgroup such as :

  free.uk.medicine.complementary

```
  free.uk.homeopathy
  alt.support.cancer
  sci.med.diseases.cancer

Regards, Ian.

I have a special oil extracted from the fat cells of rattlesnakes that
cures all cancers. Please send check for $500 for one pint.

This oil also provides artificial earth ground for all antennas.

Michael

I would avoid a 718 if I were you. They are a terrible design and difficult to repair. I own a 730, two 740s, and a 751A. I bought them all used and none worked right or at all. They were easily repaired and have very good basic designs. One of the 740s had so many things wrong with it that it took me a week to repair. I am retired and my time is free.

The 751A is about my favourite but the 740 has a better receiver. Probably because it is limited to the ham bands.

Keep us posted about which radio you buy and how the repair worked out.

Michael

Hello Michael. A friend of mine used to breed rattlesnakes. He accidentally knocked over a box of electrons and found that the rattlesnakes loved to chase and eat the shiny ones. They didn't eat the dull ones. He wonders why

```
this is.
He also threw some protons, neutrons, oldtrons and croutons for them to eat.
They liked the croutons. Some rattlesnakes liked the protons. They'd then
curl up around the mains wire and transmit to each other on 1.3GiggleHertz.

73, Ian.

So either boil it down, drink more of it, or go to the North Sea.

... not for this group, per se, but at least
it concerns an antenna.

With apologies to Joyce Kilmer, I give you my own "Trees":

Trees -- a poem for users of roof-mount TV antennas

I think it's very sad to see,
My Channel Master in a tree.

A tree with many branches prest
Against the dipoles, all distressed;

Some stormy winds quite fierce and strong,
That seemed to whistle all night long,

Blew down my mast and all that's on it;
The tree got everything upon it.

Next week I'll have to go and pay,
And buy a shiny, new eight-bay.

But meanwhile this house needs TV;
Which means I'll need to climb that tree.

"Sal"

So after you saying he lives in a world of ideal capacitors you now
proclaim that a Leyden Jar is an ideal capacitor?  Pot, kettle.

Because it's not a real world "practical and useful in actual devices"
capacitor, Leyden Jars inhale vacuum like almost nothing else in the
capacitor universe.  They are useless in virtually all practical
applications.

So Leyden Jars normally occupy the absolute bottom of the capacitor list.

I have found both electron types useful in my basement.  The spiders
think the dull ones are prey and are killed by them.  Similarly most
crawling insects are killed by the shiny ones.

You did not read that?: "> I did a search for our babbling Polish friend and
the first thing I found
> was a message posted to a Polish medical list where he claims all cancer
> is a fungus and should be treated with Epsom salts."

It was Jimp who is in opinion that Epsom salt is  appropriate for the
rec.radio.amateur.antenna.
He is right. Everyone should know that Epsom salt cures cancers.

H* Tom.

Turns out that, on my keyboard, the dot on the letter between H and J *s a
loose electron and *t's dropped off. *'m us*ng the * character to represent
the letter between H and J.
Hold on a m*nute. When was the keyboard *nvented? *f *t comes after Faraday
then *t can't ex*st wh*ch makes wr*t*ng th*s ema*l very, very d*ff*cult.

73, *an.

No. Jar is heavy weight, cardboard box is light weight. Cardboard box is
easier to stack than jars in order to increase capacity. Have to buy jars
whereas cardboard shoe boxes are usually free from the shoe shops and are an
ideal size for storing electrons.

What did Marconi say about brown shoes?

Regards, Ian.

I was thinking about using fiberglass reinforced body filler as an insulator and was hoping someone here may have some experience doing the same. It would be used to support the low impedance end of a gamma match. Power level not to excede 200 watts HF.

JImmie

Your eyes are suppose to more sensitive in the yellow area than blue.
Getting the ratio between the blue LED and the yellow phosphor right
is a major headache. Among my 4ea Ecosmart bulbs, I can't really see
much variation. However, my camera certainly sees differences. One
is rather blueish, while the others are varying shades of yellowish.
I'll try to take a phone of all 4 of them at the same time. That's a
problem right now because they're installed all over the house.

Also, another advantage of LED light bulbs is that they can be dropped
without breaking.

>I need that. Ordered 12, they're cheap. I'll give the extras to friends.

It's made for "raves" but works equally well for a fast spectrographic
analysis. There are other diffraction grating type spectrometers
available, but it's difficult to beat the price.

Sort of. I believed as you until last evening.

I finished mounting new solar panel 1 of 2 the previous day and all adhesives and sealers were very well set. Took my Vanagon camper out for a test drive and while on a freeway entrance ramp (decreasing radius of course) I heard a loud clank. Ignored it as per "driving in traffic rules" - Drive First, Worry About Noises Later.

After I got home I noticed that one of my clamp lamps had fallen off it's preferred perch. And the Edison screw base on the Philips LED bulb wasn't quite on anymore. Looking close I noticed that the metal base was a sort of crimp onto the underlying plastic. Very tiny and sharp crimps on the upper edge of the screw base. I pushed it back on. So far so good.

There shouldn't be much voltage at the gamma match feed point.

Which fiberglass filled body putty where you considering?
<http://3mcollision.com/products/fillers-and-glaze/reinforced-fillers>

Looking at the various MSDS sheets, it looks like a reasonable
insulator that's not going to absorb moisture.
My comments and guesswork in [xxxx]:

1,3-ISOBENZOFURANDIONE, POLYMER WITH 2,5-FURANDIONE AND
2,2'-OXYBIS[ETHANOL] 30 - 60%

[The volatile solvents.]

TALC 10 - 30%

[Good insulator.   Steatite insulators are baked talc.]

STYRENE MONOMER 10 - 30%

[Styrene monomer is probably propylene oxide. I couldn't find
anything in its electrial properties. My guess(tm) is that it's quite
good as styrene plastics are sometimes used as insulators.]

MAGNESIUM CARBONATE 10 - 30%

[That's chalk. It's hygroscopic and absorbs moisture. It's probably
there to remove any water from the talc, which will make talc
conductive.]

CHLORITE (MINERAL) 1 - 5%

[That's a harder form of talc. My guess(tm) is that it serves the same purpose as the soft talc, but is there to help prevent shrinkage during hardening. I'm not sure this is correct.]

FIBERGLASS Mixture 1 - 5%

[There's the fiberglass filler. Of course, glass is a good insulator. However, I don't think 1-5% fiberglass by weight is going to add much insulating ability to the mix. You might as well use Bondo, without the filler.]

FIBER 0.5 - 1.5%

[Same as fiberglass]

OXIDE GLASS 0.1 - 1.0%

[Any of a dozen glass oxides. All are good insulators]

That's a good way to determine if it will work at 2.4GHz.  However,
this is for HF, which is about 1/500th of 2.4GHz.  Some insulators
that fail at 2.4Ghz (PVC, nylon, phenolic, wood, bakelite), work just
```

fine at HF frequencies. In general, if it passes at 2.4GHz, it will probably work at HF. However, if it fails, it may still work at HF.

There's also the potential problem of volatiles and solvents. Some of the components in the body putty are hygroscopic (absorbs moisture). When baked in a microwave oven, the water and solvents may boil, resulting in cracking or crumbling. Residual ethanol solvent might make an interesting bang. Microwave baking is a fair test to see if the body filler will handle 1KW of RF at 2.4GHz, but might be a bit overkill for 200 watts at HF.

```

Loss tangent (dissipation factor) can increase or decrease with
frequency depending on material. It's measured at 1KHz, but can be
almost anything by the time it gets to microwave frequencies. For
example, glass:
<http://psec.uchicago.edu/glass/tanDelta_vs_freq_edited.bmp>

>> There's also the potential problem of volatiles and solvents. Some of
>> the components in the body putty are hygroscopic (absorbs moisture).
>
>Well if they do they will not be good even at HF.

Time to define "good". The OP proposes to use Bondo at the low
impedance end of a gamma match. That's 50 ohms. It would
considerable conductivity to put anything in parallel with 50 ohms to
have an effect.

Even placing an obvious conductor between the 50 terminals isn't going
to do much. For example, I could place a water balloon full of salt
water between the 50 ohm terminals. As long as rubber provides
sufficient insulation, there will be no dielectric loss. It might arc
over or add some capacitance depending on size, but it won't conduct
RF.

However, were he to propose using Bondo at the junction of the
matching tap section and the tuning capacitor where it hits the driven
element, there will be problems. The gamma match is a series resonant
tuned circuit at this point with high voltage across the capacitor. In
effect, the Bondo would act as part of the capacitor dielectric at
high voltages. Bondo is not suitable for building capacitors.

>> When baked in a microwave oven, the water and solvents may boil,
>> resulting in cracking or crumbling.

>
>Not a problem if it is just a test sample, but if they absorb water they
>will be a poor insulator.

Not exactly. A water soaked insulator is certain a potential problem. Yet, there are perfectly usable insulators that contain water. For example, concrete, bricks, and some pottery are contain considerable water, but are tolerable insulators, especially if glazed. HF has no effect on the water because there is insufficient energy at 2-30MHz to convince the water molecule to vibrate. The higher the frequency, the higher the energy:
   E = Plank's-constant * speed-o-light / wavelength
While building an HF antenna structure out of bricks is feasible, I would not suggest you place a brick in a microwave oven. It will get hot and eventually crumble as the water evaporates. For a higher speed example, just hit a brick or concrete block with a oxy-acetylene torch and be prepared to duck as pieces fly out as the water explodes.

>>Residual ethanol solvent might
>> make an interesting bang.
>
>I think we must be thinking about a different type of filler, all of the
>glass fibre fillers I have come across do not contain ethanol, they are
>2 part; styrene monomer and organic peroxide hardener

Please re-read my summor of the contents from the MSDS sheets. The stuff is 30-60% ethanol solvent by weight. That's needed to keep the mix flexible and compliant. As it evaporates, the Bondo hardens. However, if some residue remains, such as the result of applying the Bondo in too thick a layer, there is a real possibility of a gas explosion.

>Jeff

Well, I lied. Apparently it only gets hot and does not crumble:
<http://www.youtube.com/watch?v=aCRBeo2hsmU>
(7 mins). This has to be the most boring YouTube video ever. However,
watching the author get burned by the brick when he tries to remove
the brick from the oven is priceless.

Also, not that power line insulators are quite hygroscopic (absorbs
moisture). The surface glazing is a good moisture barrier so the
insulator insides remain quite dry. However, even a small crack in
the glazing will eventually introduce enough water into the inside to
cause arcing.

>Please re-read my summor of the contents from the MSDS sheets.

Oops... that should be "summary".

Should work OK. I vaguely recall doing it myself once years ago.
I forgot what I did, but I think I had to strengthen a base

insulator on a vertical that was fixing to break or something like
that. Or maybe I had a make a base insulator from scratch..
I forgot..
I used fiberglass body filler that had strands of fiberglass
mixed with the liquid stuff. It was fairly strong once dry,
and I don't recall having any problems with the insulating
properties.

I'm building a quad for Field Day. I have 30 feet of 1 1/2' PVC that I know will stand up with appropriate guys, because I used it to support the center of my dipole last year.

The driven element and reflector will be 8 1/2 feet apart, so I built a 9-foot PVC crosspiece fitted with a T-connector to go in the top of the mast. I'm going to put a wooden pole inside the crosspiece -- just in case I have a PVC failure. (t's cheap insurance.) The elements hang fro the crosspiece.

As described to me, this quad doesn't use spreaders, per se. The idea is to tie ropes to the left and right sides of the elements and draw them out to the sides, forming an approximate diamond shape. Hanging from 30 feet, this antenna's feed point is about five feet above the ground.

If I hang a (larger) reflector from the same height, it will effectively be slightly lower than the driven element. I do not know if I should hang the driven element several inches lower than the reflector so that they align center-to-center. I can model it. and see what happens. Because the respective shapes of the driven element and reflector will not match exactly, I'm guessing vertical alignment won't be the limiting factor.

More to come.

"Sal"
(KD6VKW)

This site http://www.frontiernet.net/~jadale/Loop.htm states that: "A properly designed Loop primarily responds to the magnetic component of the radio wave. Note that noise resides primarily in the electrical component..."

Whereas this site shows that that is not the case:
http://vk1od.net/antenna/shieldedloop.

So what is the advantage, if any, of a shielded loop antanna?

Consider three receivers:

1) Shielded loop antenna, receiver with differential input (center-tapped transformer or instrumentation amp). The two ends of the inner conductor of the antenna connected to the differential inputs and the shield connected to ground.

2) Same as above but without the shield.

3) Unshielded loop antenna, receiver with single-ended input. One end of the loop connected to the receiver input and the other to ground.

Assuming equal gains and bandwidths, would there be any difference in the sensitivity or noise level at the output of the three receivers?

None. The only purpose is to ensure balance, which helps give
deeper nulls.

But that is not the only way to ensure balance. A shield is not required for that function.

None of my AM-BC loops are shielded. I have tried shielded loops though, just to see for myself if any difference.

There no difference, assuming all of the loops were balanced and fed properly.

The mythology of loops is a lot like the various myths you see pertaining to grounds, and grounding. :|

Some claim a shielded loop is "quieter" than an unshielded loop.

I know from testing, that is pure hogwash.

Both are quite capable of picking up noise. After all, noise is RF just like any other signal, and follows all the same rules.

The true test of a small loop is how deep the nulls are.

If you can make daytime AM ground wave signals disappear by turning the loop, you are in pretty good shape.

And *any* small loop is capable of that if all is well in the world.

news:jr97r7$v5u$1@dont-email.me...

> I'm building a quad for Field Day.

< snip >

> More to come.

Today, I modeled the 20m quad antenna with EZNEC. It looks good at 75 ohms feedpoint impedance, with the entire phone portion coming in under 1.5:1, post-tweaking. It was promoted to me as a nominal 52-ohm antenna but the SWR was a half-point higher when I swept it at 50 ohms. I have no problem feeding it at 75 ohms; that's exactly what I did with last year's dipole. The model had just over 9 dBi gain at a 40 degree takeoff angle. At a 25 degree takeoff angle, the gain is still a respectable 8.0 dBi

At first look, I'm surprised to see how sensitive the tuning of the driven element was to the height of the feed point above the ground. That seems to have a more profound effect than the length of the driven element. I'd have to play with it some more to know for sure.

I wondered about the effects of the vertical position of the reflector. I moved it around in the model and it seemed to have only minor effect on the parameters. Reducing the size of the reflector sharpened the SWR dip without doing much of anything good. I'm staying at 5% when I build.

The reflector is called out to be 5% larger than the driven element. This is at odds with other quad designs I found on the Internet. The want about 3%. The difference may be that a 3% larger reflector may be better for a tower-mounted quad, while this design is quite close to the ground.

Only 1.4:1 where resonant.. Shouldn't be a problem unless maybe
you stray down the band a good ways.. May not be much of a problem
on 20m.

Probably not hugely critical in the overall scheme of things.
And with the variances of the location and setup, completely matching
the model will probably not happen.

I haven't done field day in a few years.. Getting lazier and lazier
I think..
I have a pretty good setup for field day, but I have to feel pretty
motivated to drag it all out.   :/
I've got a short tilt/crank tower, and a A4S. I can haul it all
on a motorcycle trailer. Actually, the tower will fit in the back
of my truck, but I later started using a trailer, as it seemed easier.
Here is a view from above one year..

http://home.comcast.net/~nm5k/fd01-1.jpg

This is from a later year when we were setting it up.
That is my old truck and trailer.. "It's a 68 F-250, which I still
have". You can see the motorcycle trailer on the back.. It's made
from a VW axle and tires... Has shocks and rides smooth.
You can also see my plastic bugcatcher on the truck bed. That's
the 11 ft center loaded version. Works 80-10.. It's 14 feet if
I add the three foot solid Hustler mast to the base. Which puts
the coil up at eight feet.

You can't tell it from the pictures, but that tower is *very* stout.
It's using a heavy base a friend of mine cut at a shipyard, using a
plasma cutting table. You can stick the antenna on the tower, and
crank it up, and it will stand up by itself, even with no guy wires,
or anchoring the base down.
Of course, I do guy it just to be on the safe side.
They supposedly won 10m phone with that A4S one of the years I
brought it.
Myself, I hardly ever used the thing out there.. Others do..
I always stick to the low bands on CW at night. 160,80,40..
And I prefer just coax fed dipoles for those bands.
That antenna has always worked well so far.. It's basically
full size, even on 20m. "32 ft elements" And it uses a separate
reflector for 10m, which gives a more optimum spacing for that band.
It's three elements on each band. If I remember right, the antenna
is about 31 ft up when fully cranked up. Not real tall, but good
enough considering it's 20-10m.

Do you use them to the "direction finding"?

"The advantage of this feed arrangement is that the coaxial feed typically enters the loop opposite to the gap, and if attention is paid to symmetry of the loop and feed, the balance that is achieved. Best balance yields the deepest null which is important in direction finding applications for instance."

Hello, and a loop (dipole) antenna doesn't "respond" to just the magnetic (electric) component of a propagating electromagnetic wave. A (receiving) loop or dipole antenna intercepts the incoming electromagnetic (EM) wave. Last time I checked an EM wave had both electric and magnetic components. Just because an orientation of an axis of the antenna resulting in maximum signal strength is parallel to the electric or magnetic component of an EM wave doesn't mean that it's responding to just that component.

I wish hams and others would quit trying to redefine electromagnetic theory. Hams have designed and constructed novel and practical antennas over the years but their explanations about how they work are often just plain wrong. Sincerely, and 73s from N4GGO,

I agree with your second link (by VK1OD).

The time varying magnetic field generates an electric field and that is received by the loop.   When you screen it completely, it doesn't work, you need the gap.

By placing the gap opposite to the feed point, you get a balanced loop without the need of ferrite or other constructions. If you can get balance via other means, you don't need the screen.   Balancing the loop reduces noise due to common mode issues. This isn't different from using a balun between a coaxial cable and a symmetrical dipole.

Your option three may behave competently different, as the coaxial cable, power supply cable, switch mode power supply, etc may contribute to reception of signal and noise due to common mode to differential mode conversion.

From my experience (reception) with electrically small well-balanced indoor loops and indoor dipoles, I found some advantage of the loop over the electric dipole at low frequencies (say below 3 MHz). I contribute this mainly because of the nulling capability. Whether is applies to your location depends on the field distribution of the noise at your location.

At higher frequencies there is difference in S/N ratio, but not in favor of one antenna. Sharp nulling wasn't possible. So to know what option is best for you, you need to try it. Maybe install both options and select the antenna that gives best results as this will depend on frequency and the angle of arrival of the radiation you want to receive.

Other thing that may really help is to find your local source(s) of noise, use lots of ferrites and try to find a sweet spot for best S/N ratio.

Amateur radio DF on VHF (very popular) tends to use yagis.
Loops seem to be used more for MW and HF DF.

Regards, Ian.

The explanations are wrong because the radio waves are simply the electric
waves or the electron waves.
From this point of view the next is obvious;
"Since the directional response of small loop antennas includes a sharp null
in the direction normal to the plane of the loop, they are used in radio
direction finding at longer wavelengths. The loop is thus rotated to find
the direction of the null."

" Although a similar argument may seem to apply to signals received in that
plane, that voltages generated by an impinging radio wave would cancel along
the loop, this is not quite true due to the phase difference between the
arrival of the wave at the near side and far side of the loop."

No. I use them for MW broadcast reception.
I generally don't use them much above the 160m band.
My largest loop covering from longwave to about 2 MHZ,
using switchable caps.

Hello, and they are most certainly not "electric" waves.  What part of
"electromagnetic" don't you understand?  (It's just this kind of stuff
that prompted my previous post)  I take it you're not an EE or have ever
taken any undergrad/grad courses in EM theory.  In any event someone
else can continue this starting-to-drift off topic thread.  Sincerely,

Yes. I expect most of the work to be between 14.220 and 14.340, where the SWR is acceptable. I have no problem using the tuner in my RS-870 to show the radio perzackly what it wants to see.

> And with the variances of the location and setup, completely matching
> the model will probably not happen.

Yeah, I get that.   The reasons I modeled it at all were (1) to verify that I didn't have any gross errors and (2) to play with the parameters so I could see what effects resulted from certain changes. I'm thinking of putting the analyzer on it (or transmitting tune power into it and tugging or slacking the guy ropes on the left and right corners of the driven element for a good match. After I get it up, I'm limited as to what I can do with the driven element length. I did consider putting a telescoping section into the driven element, tuning and then then soldering in a replacement of equal length. I don't think I'll go that far.

Some quad designs that I saw online depict an adjustable length section in the reflector. It's shown as the reflector conductors coming down to their low point where they are several inches apart and then being bent to go parallel, with a shorting bar placed (selectively) across the parallel-running conductors. This effectively provides a length adjustment for the reflector. Since this is my first quad, he learning curve is still fairly steep.

> I haven't done field day in a few years.. Getting lazier and lazier

> I think..

I'm getting there, myself. Age = 69. Club President, FD Chairman, VE,
Multi-elmer. I have a hard time saying "no."

This year we're using N3FJP's Field Day Logging software for the first time.
While it will make for instant dupe-checking and a very fast dupe sheet
generation for the report to ARRL, getting it set up has consumed many
hours.

Thanks for the pictures. Maybe I'll do a yagi beam next year. I've had
them for many years on 2m & 440 but never a one for HF.

73,
"Sal"

Yep.. Sounds like you are fairly locked in.. :|
These days, if I really wanted to do field day, I generally
prefer to go up to my own land, if I'm going to go to all
that trouble. That way I can do other things I need to do,
when taking a break from the radio.
Exciting stuff like mowing grass, clearing brush, etc.. :+

But I really don't care for contest/field day type of
operating all that much. About the only reason I did it,
was to help pad the club's scores a bit.
Being I work only CW, I can rack up some decent points if
I feel motivated. And on the bands I work, they are swarming
like flies..
One handy thing about the puter logging is being able to see
if what you are hearing is a dupe or not, without having to
scan sheets of paper.

But generally, my idea of "field day" is kicking back in
one of my lawn chairs, sipping on a cold adult beverage,
and talking to all those good ole buoys on 75 or 40...   :/
I already have dipoles strung up there, so all I have to do
is unroll the coax, connect to the radio, and I'm off to the
races.

The Earth is in space and the spacecraft also.
The same is with aircrafts and autos.

All transmitters and receivers are connected with the mass.

Radio transmitter is an electron pump.
But without the "infinite source or sink for charge" it do not work.
>

Without the "infinite source or sink for charge" a transmitter is gaining a
rather large positive charge.

It is theory of Faraday, Lorenz, Marconi, Tesla and Dirac.

Who is the authors of yours?

It is a pity that you are not a radio amateur yourself.
If so, you could see with your own eyes (or feel with your own hands)
that this is not true, and so the whole theory is incorrect.

But maybe you have a cellphone.  Try making a long call while you stand
on one of those glass tables that they use in static electricity
experiments.
See if you develop a positive charge while making that call.
(and not doing other things like stroking your cat)

Mine aren't.

The way you talk about radio reminds me of a friend who used crystal sets back in the 1920s. Fortunately, hew was able to learn modern radio theory and practise.

I've a recollection that you've posted your views onto this newsgroup a few weeks ago.
I guess that asking you to disregard 19th century understanding and learn 20th and 21st century understanding is probably an unproductive approach.

Regards, Ian.

Many things do not have a chassis or anything that could even remotely be
called a chassis.

You are an idiot.

No, it is not.

You are an idiot.

> Who is the authors of yours?
> S*

Modern science.

And you are an idiot.

Many thanks for your time Gents, The antennas were intended for outdoor use and constant handling. being encased in hard plastic obviously enhances those functions. My experience has been at the other end of the spectrum so to speak and I (incorrectly) assumed an antenna picks up an electrical signal. Putting a layer of insulating plastic on it seemed contradictory. If antenna is detecting magnetic signals obviously a different story.

When I mentioned impedance I mislead you. Wasnt referring to antenna impedance but the impedance looking back form the recieving antenna to the signal source (thats what us old analogue designers do, Norton/Thevenin equivalent circuits etc !!!!)   and the effect on that a layer of plastic has.

Your combined efforts have answered a lot of my questions, thanks for your time.

Cheers
John

With a Hand Held Radio - the person holding the transceiver is the ground plane. Because the human body is comprised mainly of water, it acts like the missing half of the antenna.
Radio waves in front of the person is radiated, radio waves behind the person is blocked to a small extent because of the water in the persons body.
This is the reason why Rabbit Ears antenna's do not work in concrete apartment buildings with people moving around the room.

The person who is walking around blocks some of the reception - especially in the higher frequency ranges because anything one or more wavelengths in size can and will block a signal.

I'm surprised that no one caugth the foopaugh that the origional answer giver had made when he described how a antenna works.

The reflector has to be a certain size for a certain wavelength and there is only one driven element.
The other elements - also known as directors - gathers the signal and directs them backwards in the array towards the reflector.
Each director gathers the same amount of signal as a dipole and each director adds gain to the antenna at the expense of beam width.

The only way to increase gain is to give up something somewhere else.

If you stack two antenna's one above the other - one wavelength apart - and build phasing lines, each antenna will only agument the other by a gain factor of 2.85 - reguardless of how much gain the origional antenna had.

If you stack two beam antenna's, one or more wavelengths apart - the apature becomes smaller - hence if you put enough of them together, it is as if you were trying to look through a straw while driving an automobile.

The beam width becomes very narrow, while increasing forward gain to the point of infany.

With a UHF signal - eventually when it runs out of things to bounce off of - it just travels in a straight line - out into space, never to be recovered again.

I think the OP was asking about receiving antenna's and not transmitting antenna's.

A receiving antenna - works best when it is cut to one individual frequency, but those antenna's tends to be more expensive, not less, because they have to be purpose built.   The size and spacing has to be more exact to get the results the buyer is looking for.

While a VHF antenna, with the use of phasing lines, a person can make a very broadbanded antenna and it will still work up to the length of the longest combined element.
When the elements are too long, the antenna can look back through the array and can match the wavelength to the elements in the array...

<sz.bialek@wp.pl> wrote:

>Radio transmitter is an electron pump.

Prove it. Show me a way you can detect your mythical electrons coming off the antenna. Or better yet, explain to me why common methods of detecting electrons (fluorescence, phosphorescence, Wilson cloud chamber, electrometer, electroscope, etc) fail to detect your mythical electrons.

>But without the "infinite source or sink for charge" it do not work.

How large is infinite? Does that mean that radio only works when I can't measure it?

>Without the "infinite source or sink for charge" a transmitter is gaining a
>rather large positive charge.

Amazing. I put my voltmeter on the case of my HT, and there's no DC voltage when transmitting. Same with various HF transmitters. Perhaps my radio is not infinite enough.

>Tesla made the electron beam and next the X-rays.

Electron beams (cathode rays) were discovered by Johann Hittorf in 1869.
<http://en.wikipedia.org/wiki/Cathode_ray>
X-rays were correctly described by Wilhelm R�ntgen in 1895.
<http://en.wikipedia.org/wiki/X-ray>
Please have you history recalibrated.

>They are connected to the mass (chassis).

Where is the chassis on my HT, TV antenna, dipole, satellite antenna, and other antennas that are not grounded? They seem to work equally well with metallic, insulating, and unsupported mounting arrangements. Also, without I ground, I presume aircraft communications also does not work?

>> Now, that we have the requisite science fiction out of the way, could
>> I trouble you to answer my original question.
>>   Is your theory that if you repeat the same garbage over and over,
>>   eventually someone will believe it?
>
>It is theory of Faraday, Lorenz, Marconi, Tesla and Dirac.

Some of their early guesses were wrong. It was bad enough that when Lee De Forest had to defend his patents in court, he could not explain how they worked. I don't care if your theory came directly from the radio gods themselves. If your theory cannot stand up to simple scrutiny and real world examples, then it's garbage, no matter from where you excavated it.

Anyway, you didn't answer my question (3rd try). Do you believe that repeating the same wrong theory over and over will somehow make it correct? Or perhaps your plan is to wear everyone down with your one line incorrect and unsubstantiated claims, in the hope that we will become tired of your games and go away? Or, are you simply craving for attention?

>Who is the authors of yours?

I haven't presented a theory. I've only shot holes in your theory. I don't need the testimony of dead scientists to demonstrate that an ungrounded antenna still functions and that antennas do not belch electons.

Incidentally, if you had a clue, which you apparently do not, you might read up on photons, which are the carriers of electromagnetic force, including RF.
<http://en.wikipedia.org/wiki/Photon>

The earth and spacecraft are floating around in a vacuum, same as
between your ears.  I think you'll find it rather difficult to
demonstrate a conduction path through a vacuum for your grounded
antenna theory.  Besides, if outer space did provide a conduction
path, it would also short out the antenna elements.

>The same is with aircrafts and autos.

Aircraft and autos do not operate in outer space.

>All transmitters and receivers are connected with the mass.

What mass of outer space?  There is roughly 1 hydrogen atom per cubic
centimeter in outer space.  That's not much mass and certainly not
enough to ionize and produce a conductive path.

Gents,
Sorry about delay in getting back. After I sent first message my ISP fell off the perch and only now has come back on. Funny how you can get a response from a voluntary organisation within hours but somebody you have a contract with takes days!.
I havnt read all your replies yet but will do now, sounds from the numbers there is a controversy.
Once again thank you for your expertise.
Regards
John

Not quite right, since you don't have to actually "block" the signal for it to happen, but Mr. Blaupunkt wouldn't have a clue anyway. It's more about the whole wavefront, amplitude of the parts of same, phase, and interaction with the surrounding conductive and absorptive environment. Some of which can be alive, filled with salt water, and move.

Here is the 'T" antenna I referred to. It is totally plastic.

http://www.happywanderer.net.au/page.asp?parentid=19&parent2id=24

If link doesnt work the website is www.happywanderer.net.au and the image
is on first screen. The totally plastic covered yagi I saw was somewhere in
ebay. I,ll see if I can find it again.
Regards
John

And the yagi,

http://www.ebay.com.au/itm/Caravan-Remote-Controlled-AussieVan-EasyTune-TV-Antenna-Aerial-/200739737936?pt=Caravan_Parts_Accessories&hash=item2ebd055150

The argument I seemed to have inadvertently triggered reminds me of
disgreement
I had about 40 years ago describing Op Amp inputs as virtual earths.
Odd how equally intelligent and educated people can look at things
differently.
Cheeers
John

I liked the reflector screen on the HW-DT8. It's appears just a bit sparse for the frequencies it's supposed to cover.

Other than that the driven part is kind of interesting. If it's reasonably priced enough and shipping isn't out of line I may order one just to see what mischief they are up to.

tom
K0TAR

Link to the antenna I referenced.

http://www.happywanderer.net.au/page.asp?parentid=19&parent2id=71

And of course it will give me a nice new antenna to perform weight and charge measurements on.

Can't use an old one. See, when the antenna gets used more and more it gets tired because of electron loss. You have to watch your transmit and receive balance. If you don't you will end up with too few electrons around, which makes for an increase in transmit resistance. Some people think it's impedance, but they don't know it's just because you haven't got the right length coax.

And the other way around, if you receive all the time you eventually fill the electron sump, and the antenna must be discarded unless you can get a good electron sump pump for cheap. Funny thing, that's why the old AM and FM radios wore out - they were full.

>Why does anyone answer Skeezix Blutarsky?

Because I'm terrible at resisting temptation. If someone wants to make themselves a target, it's far too tempting to take a few shots at the target. Also, I enjoy reading (and writing) science fiction. However, the real reason is that I haven't seen any decent antenna related discussions in this newsgroup for a long time.

Its why you should never leave a powerpoint switched on. You end up with a
heap of electrons on the floor.
And a hole under the neutral hole.

Unfortunately the clueless idiot from Poland has woken up and is
making his outdated claims again...

What you should know is (and apparently have realized by now) that
the antenna impedance is not an impedance between its elements and
the surrounding air, but a "radiation impedance" that results from
the antenna emitting an electromagnetic field.   This field traverses
plastic, a vacuum, air etc without problem so it does not matter if
you coat the elements.

A cristal sets has the modern name "rectenna":
"A simple rectenna element consists of a dipole antenna with a diode
connected across the dipole elements. The diode rectifies the AC current
induced in the antenna by the microwaves, to produce DC power, which powers
a load connected across the diode. Z: http://en.wikipedia.org/wiki/Rectenna

But I hope that you understand that 19th century physics and 21st century
are the same.
In the 20th the all was a top secret.

There no contradictions:
"In April 1887, Tesla began investigating what would later be called X-rays
using his own single terminal vacuum tubes (similar to his patent #514,170).
This device differed from other early X-ray tubes in that it had no target
electrode. The modern term for the phenomenon produced by this device is
bremsstrahlung (or braking radiation). It is now known that this device
operated by emitting electrons from the single electrode through a
combination of field electron emission and thermionic emission. Once
liberated, electrons are strongly repelled by the high electric field near
the electrode during negative voltage peaks from the oscillating HV output
of the Tesla Coil, generating X rays as they collide with the glass
envelope. He also used Geissler tubes. By 1892, Tesla became aware of the
skin damage that Wilhelm R�ntgen later identified as an effect of X rays."

Tesla and Marconi  proved that antenna must be grounded and that it
emmits/gains electrons.

Photons are in the teaching program as a simplification.
In physics are the wave packets.

No, they did not.

Today we know that SOME types of antennas work better if grounded and that
there are no electrons gained or lost from antennas.

You are a babbling fool.

Hello Sal.
Ah well, I guess that some of us like to try to be helpful. I'm hoping that
Szczepan might one day read some modern books on radio theory and practice.
Reminds me of when I had a relative who was unable to accept and understand
modern day life and technology. Tried to help but relative was incurable.

As someone else has said, we've had some good discussions about antenna
theory and practice.

Regards, Ian.

I don't recall us having nuclear bombs in the 19th century, nor transistors nor integrated circuits. The underlying physics may not have changed but man's understanding of it certainly has.

By analogy, the human body is still the same design as it was in the 15th / 16th /17th centuries (and earlier and later). If you need a doctor, will you go to one practising 21st century medicine or 15th century medicine?

Would you prefer to drive a 21st century car or a 19th century car? Would you be worried about dropping off the flat earth?

Perhaps you should study the "phlogiston" theory. How about the opposition that Galileo encountered when he tried to support the theory of Copernicus that Earth orbits around the Sun? If you'd been around in the time of Galileo and Copernicus I guess you'd be certain that the Sun orbits the Earth. After all, that's how Ptolemy said it was and that view lasted a thousand years or more.

Regards, Ian.

Ah no, Marconi showed that HIS antenna worked better when connected to ground. He definitely did not prove that all antenna must be grounded because many antennas in common use to-day (for example the quad and the yagi) weren't invented until long after Marconi's experiments.
Several people have told you the same thing. Some of those people hold amateur radio licences and will have built and operated antenna which definitely are not connected to ground so they'll know what works.

Any truth in the rumour that you live in the central USA and hold an Extra Class licence?

Regards, Ian.

Well, with Field Day coming up, I had planned to use last year's 20m dipole again, but I was on the phone with a guy last night and he dictated some really easy-sounding plans for a two-element quad. It's supposed to be good for 6 dB more gain than a dipole. Yes please, I'll take one free S-unit. We're in the southwest corner of the country, so aiming it is a no-brainer.

Maybe I can post a diary of the build to amuse you nice folks by demonstrating my (lack of) skill using hand tools. By the way, we'll be using N3FJP's "Field Day Network Logger" this year, for the first time. Last year, one of our guys used N3FJP single-station logger for himself (400+ contacts) and he registered the network version for the club. I like it. We've had several good trial runs. Find it at http://www.n3fjp.com/.

Hello courteous, dedicated and hard-working (over-worked) Sal.

After that write-up you may get a posting from a certain person telling you to use a 19th century antenna rather than a modern one. So much better for throwing those electrons into the aether :-)

I'd be delighted to read your diary. Your hard work will save my hands from Bandaids and other first-aid treatments. I like to learn through other's pain. Actually, a two-element quad might be a project for 2013 for me - not sure if my yagi is still fit for work on 20m - 15m - 10m. Homebrew quads used to be popular here in the UK some decades ago.

73, Ian.

It is probably what is called a "folded dipole."

We used to make them out of common TV twinlead. They have a characterisstic impedance around 300 ohms, same as the twinlead, so the black block at the hub is likely to be a 300-75-ohm balun (trannsformer) to match the coaxial cable lead-in.

You determine the frequency of interest and cut it to size, accordingly. They're not too great for wide-band coverage, but you might get lucky. (The wide-band issue is why big, expensive antennas always have elements of many different sizes. "One Size Fits All" definitely does NOT apply to antennas.

Much better. Field Day is the prime incentive to do last minute
repairs on antennas and equipment. It's also a great place to do
testing that should have been performed before Field Day. Learn by
Destroying at its best. While fatalities and major injuries tend to
be minimal, I can't say the same for equipment and antenna failures.
Somehow, the miracle antenna contrived specifically for Field Day just
doesn't seem to tune or work as expected. Your "easy-sounding plans"
should be an ominous warning of problems to follow.

I'm staying out of Field Day this year. I had planned to deploy my
inflatable antenna design, but decided that doing R&D on top of a
mountain was not a good idea. I plan to visit, but not operate much.
I did my part this morning by customizing one of the Field Day
trailers with my cutting torch. Hopefully, I didn't weaken the
structure so that it will collapse on arrival to the site.

>Maybe I can post a diary of the build to amuse you nice folks by

Any tool can be used as a hammer. That should be fun to read, and
more fun to watch the video.

>By the way, we'll be
>using N3FJP's "Field Day Network Logger" this year, for the first time.
>Last year, one of our guys used N3FJP single-station logger for himself
>(400+ contacts) and he registered the network version for the club. I like
>it. We've had several good trial runs. Find it at http://www.n3fjp.com/.

We like to use N1MM, mostly because it's free, but also because it
took the last half dozen Field Days to train the operators in its use.
<http://n1mm.hamdocs.com>
We also gave up on running CAT5e all over the site because of the RFI
generated, but also because I got tired of dealing with trashed rolls
of CAT5e as everyone seem to enjoy walking on or tripping over the
CAT5 and coax cables. We tried 802.11g wi-fi, but found that high
power transmitters are really good at blocking the receiver front end
of the wireless cards. Since we don't run more than one station on a
band, there's no issue with dupes. So, no network needed.

>(Jeez -- what am I _not_ doing?)

Operating?

Not quite totally plastic. Inside the ABS or PVC tubing are some wires. Most likely, a length of twinlead forming a folded dipole. While not the most sophisticated antenna available, it's probably sufficient for campers and caravans.

However, there's a small problem. If you cram an antenna into a PVC tube, the resonant frequency goes down. There's no set value for the velocity factor for PVC or ABS, so the resonance change will vary with manufacturer, doping, and the position of the moon. It's not a big deal for a low-Q minimal gain and wide band antenna such as this folded dipole. However, as the gain goes up, the tolerances for element lengths become more critical. This means that changes in effective length and resonance caused by PVC or ABS pipe becomes an important consideration.

> > Capacitive coupling, I suppose at the frequencies involved there would be some.
> > If it works as well as all metal why doesn,t every one use it and stop corrosion?

The distance between the metal elements and the dielectric (PVC or ABS) is also a consideration. Obviously, if the pipe diameter were fairly large, the effect of the pipe would be minimal. Similarly, if the pipe were molded around the conductor, the effect of the pipe would be maximum.

There's nothing magic about coating an antenna to prevent corrosion. This is an important consideration for trailers, campers, and caravans. The antenna has to survive freeway speeds and be fairly aerodynamic. Coating the antenna with smooth plastic does this.

If you feel ambitious, and happen to have either a grid dip meter or an antenna analyzer, just build any resonant antenna (probably at VHF frequencies) and watch the resonant frequency change as a PVC or ABS pipe is slid over the antenna elements. I build a collinear antenna out of alternating pieces of coax cable. It tuned perfectly, until I slid the antenna into a PVC pipe. Tuning changed from 146MHz to a useless 135MHz. Filling the pipe with urethane foam (fence post compound), lowered the frequency a few more mHz.

Sound warning, indeed. I checked some websites devoted to quads and the measurements are in the ballpark. The 20m version is fairly close to the ground,, being suspended from a boom at the top of a 30-foot pole. I'm going to build it and try it in my yard before taking it to FD. The 30-foot pole is no problem; I had three of them last year for the dipole.

Summary: Short reminder for unmoderated newsgroups that crossposting is permitted
Keywords: FAQ, ham, amateur, radio, moderated, unmoderated, crossposting,
permitted

Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.2 2011/11/02 04:08:53
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/
d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. After a successful trial |
period (90 days, through early July 2009), we decided to adopt this |
change permanently. |

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

> earphones".

And what the electrons do in such instalation:
http://www.telegraph.co.uk/technology/3336114/Over-to-you-Mythical-electricity.html
"
  a.. It is very simple to light a building with power stolen from a nearby radio transmitter as a farmer once proved with a barn.
  b.. 1. Ensure that the building is isolated and near a powerful transmitter
  c.. 2. Fit it with a metal roof (corrugated iron works well)
  d.. 3. Connect the lights between the roof and a good earth connection
  e.. 4. Bask in the glow
There no the "crystal" or a diode.
What do you think. Will it be working with the diode between the light and the roof ?

Where come from the electrons?

Galileo, Copernicus, Ptolemy. All known that the planets orbit the Sun.
But the teaching program "said" the "the Sun orbits the Earth."

The same is now.
All physics people know that : "Light is the oscillatory flow of electrons".
But in teaching program are mystery TEM waves.

That is your task to find out.  We all know they were wrong, it is
only you that keeps coming up with that electron emitting bullshit.

Did you read the final comment - "I am afraid that Peter Stuart has been misled. There is not the slightest chance of "tapping in" to the power being radiated even from the highest power stations". That came from someone who ran high power transmitters.

How much power input or output does a transmitter have to have in order for it to be a "powerful" transmitter? I have a 400W transmitter around six miles away and a 200kW transmitter around 50 miles away. Which one's signal will be the stronger at my house?

How accurate are science based reports in the Telegraph?

Regards, Ian.

"Some people" consider the Fresnel's idea and Heaviside's equations as authoritative.

"" In 1817, Young had proposed a small transverse component to light, while yet retaining a far larger longitudinal component. Fresnel, by the year 1821, was able to show via mathematical methods that polarization could be explained only if light was entirely transverse, with no longitudinal vibration whatsoever.
From: http://en.wikipedia.org/wiki/Fresnel

But some people know that Young is right and that: ""Light is the oscillatory flow of electrons".

This small transverse component is because the light is radiated by dipole.
Radio waves radiated from monopole are the pressure waves (oscillatory flow).

And what is your opinion about Wiki:
"It is now known that this device
operated by emitting electrons from the single electrode through a
combination of field electron emission and thermionic emission. Once
liberated, electrons are strongly repelled by the high electric field near
the electrode during negative voltage peaks from the oscillating HV output".
From: http://en.wikipedia.org/?title=Nikola_Tesla

I hope that you accept the word "electrode" in place of "antenna's end"
S*

This comes after my earlier reply about wanting to see the model.

When I did the modeling mentioned above, I modeled the dipoles in a fan configuration connected to a common short connection and varied the angle between the dipoles and the length of one dipole.

I just did another series of models this time as parallel dipoles separated by 6 inches connected to a short (1 inch) common section for the feed point.

The top dipole was set to be roughly resonant at 30 Mhz and the lower dipole was initially set to be twice as long.

After saving the SWR plot, I repeated for length ratios of 1.5:1, 1.25:1, 1.1:1, and 1.05:1.

Short summary:

The top dipole remained fixed in length but the lowest SWR point shifted slightly for the higher frequency.

The lowest SWR's at both frequencies were both under 1.5:1 over the range of 2:1 to 1.05:1 for the length ratios.

Therefor either fan dipoles behave differently than parallel dipoles or I screwed something up in the previous run.

I'm going to have to run fans again and this time save the results.

If anything interesting turns up, I can put all the data on a web server somewhere and post it for those interested.

Summary: Recruitment announcement for ham-radio-related FAQ articles
Keywords: FAQ, Intro, amateur, ham, radio, recruit, recruitment

Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/recruitment
Revision: 1.2 2009/11/25 14:41:01
Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team.  We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

 radio/personal-intro
 Subject: Guide to the rec.radio Newsgroups
 Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
 Last Posted: 9 Nov 2001 06:18:17 GMT
 Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article       |
is that it does not mention newer amateur radio newsgroups created since      |
it was written, including:                                                    |

 rec.radio.amateur.antenna                                                    |
 rec.radio.amateur.boatanchors                                                |
 rec.radio.amateur.dx                                                         |
 rec.radio.amateur.equipment                                                  |
 rec.radio.amateur.homebrew                                                   |
 rec.radio.amateur.moderated                                                  |
 rec.radio.amateur.space                                                      |
```

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

Anyone have good success with a noise filter power bar? I am looking at the Monster Power Blackout HDP 660.

I am getting a lot of electrical noise, RFI and I know some comes from the TV, but when TV is off there is still some anoying noise that I am thinking a EMI RFI Noice filter would help to reduce this. The rig is 40 years old.

Anyone have any cheap comments regarding any power bar or surge protector that have the best RFI EMI noice filtering?

Thanks
73s

Probably a dumb question, but is the noise for sure coming in through
the rigs power plug? You took off the antenna and the noise is still
there right? Cause if it's gone with the ant off a power line filter
won't help much.

Monster products are something any EE wishes they thought of, but none of them did because they are a ripoff, at least from the price/performance perspective and engineers normally aren't in that business.

Oxygen free copper, ways of winding the strands so they work better, all BS when it comes to signal delivery and the ability of the human ear to perceive it. It's almost as bad as damping factor.

I love the line voltage regulators they sell. Like the voltage regulators in every single piece of equipment plugged into the line don't work.

Those types of products are something any EE wishes they thought of, but none of them did because they are a ripoff, at least from the price/performance perspective and engineers normally aren't in that business.

Oxygen free copper, ways of winding the strands so they work better, all BS when it comes to signal delivery and the ability of the human ear to perceive it. It's almost as bad as damping factor being meaningful.

I love the line voltage regulators that some sell. Like the voltage regulators in every single piece of equipment plugged into the line don't work.

I agree with the comments here. I doubt you will get success with this product or improvements with any Monster product.

I had a microwave that made noise in my receiver, a lot. It was coming in from the antenna, not the power line. I figured the microwave was radiating noise into the power line and thence to my antenna. I took the microwave apart and installed an inductor capacitor module to suppress the noise within the steel cabinet. That worked. These modules are not cheap, even on ebay. Getting a module like this for 15 amps cost me 27 bucks on ebay. \

Once you let the noise out of the enclosure into a power cord, the power cord will radiate even if there is any suppression at all in an external filter.

Like I said, you will need an inductor capacitor filter mounted inside your tv or other device that is radiating emi. Most people are unwilling to get that serious about things.

There is another horrible possibility. A friend who lived in an apartment got terrible noise from an adjacent apartment that had a large plasma tv. LCD tvs don't do this. The noise was actually radiating directly from the screen. Nothing to be done. He got them to take back their new tv for full credit and buy an lcd tv. He sweetened the deal with 100 bucks. LCD tvs generally cost a bit more than plasma.

As was already said, take off the antenna and if the noise goes away, a power line filter will do nothing.

Michael

Just a skoshie clarification, if I may. Can we please restate that that only applies to power line filtering on the victim device? You said it nicely in your earlier text, but the summary sentence [quoted] left an opening for the reader possibly to rule out all power line filtering.

I hope this helps.

You haven't yet said if you tried disconnecting the antenna and whether
or not the noise was still there. That's the first test, and the best way
to determine if the noise is coming through the power line or the
antenna.

Sometimes we forgot the advice suggested in earlier
posts which might have cleared the problem or put
us on the right track. It was a very worthy point and
I just wanted to be sure AJL followed up on it.

It is nice to see things running smooth here again.
I truly consider this one of the best groups available
for hams -- antennas are sometimes very difficult
to understand and I've seen a lot of positive advice
here -- and learned a lot as well!

You don't need a good match, particularly at lower frequencies where atmospheric noise dominates. You want low impedance (static and all that).. what about a loop and a transconductance amplifer (current in)..

You're not building a transmitting antenna or trying to get the best possible noise figure, so match isn't a big deal.

You could probably use a resistively loaded whip and be done with it.

In fact, try a few meter vertical or something like that before you work too hard.

I use one on my PCR1000 and it works pretty well. Sure, I'm not going to dig out those faint signals, because they're overwhelmed by the noise from other areas.

The other thing you might find useful, and simple, is to use two crossed vertically oriented loops and make it possible to switch between them. Then, you could place the null on a potential inteferer.

But I'd start with something like 10-15 feet of wire and see how it works.

It's quite possible that poor or no feed line decoupling could be a
culprit also.
With no decoupling, the coax will pick up shack/house noise on the
outer side of the shield, and pipe it back to the receiver on the
inside of the shield. Assuming coax anyway..
Of course, far off noise is more likely to be received by the antenna
itself, and even a system with a decoupled feed line would still
receive the noise.

A power bar isn't going to help much:
<http://www.powerbarstore.com>

As others have suggested, find the source of the noise, and then think about solutions. In my house, it's the multitude of wall warts and switching power supplies that generates the bulk of the noise. These switchers turn off when not charging or powering anything. So, no noise when they're plugged in, but not being used. Consider using clamp-on split ferrite filters if you suspect that the noise is being conducted down the power line.

Light reading:
<http://audiosystemsgroup.com/SAC0305Ferrites.pdf>
Although the article is on audio noise suppression, it applies equally well to RF noise suppression.

Thanks for the great advice, I never thought about unhooking the coax to
eliminate that but I know there is also noise coming from the plazma tv,
when it is on, I hear the static, and it immediately stops the static when
the TV is shut off. Now I have read that the screen can transmit through air
the interferrence. I will try the coax unhook today to see isoloate more.
That just makes so much sense. Thanks again and I will try this today.

Hi, We have a 40 foot galvanized aluminum antenna tower attached to our house that we don't use & I was thinking about selling it. There are four ten foot sections & the top has some kind of box looking thing & round antenna rods. Any ideas on what its worth, anyone want to buy it? I'll take best offer I guess-you dismantle & haul. Located in London, KY about 10 miles west of I-75, exit 41.

What is it worth?

Any offers?

Call 606-877-9912 or email to kopy@hughes.net if interested

It can not be galvanized aluminum. If galvanized, it is steel. Anyway, if it is what is called Rohn 25 and was already down and in good shape, it would be worth about $ 35 to$ 45 per section, or about $ 160 total. If someone has to take it down, whatever you can get for it.

If some other type, maybe even less.
Rohn tower has 3 round legs about an inch in diameter and round cross bracing, about 1/4 inch in diameter that ziz-zags up the sections.

Up here a lot of folks give them away to anyone willing to dismantle and haul it.away Try to think of it as a liability lightning rod and maybe kindly give it away to some ham who would love to have it. The stuff up top may be worth something to some ham, but you aren't using it anyways. If you ask around the ham community you can always find a young ham struggling to better his station on a shoestring budget.

Having worked in the tower industry - not all tower with lattice is automatically Rohn.

There is all different grades of tower, and my guess is that this is TV tower - not the heavy duty Rohn - but I could be wrong.

I also could not blow up the picture to get a closer look - to see if it could be a Rohn 45 series of tower - you never know.

Some things to look at which will distinguish one tower from another, the size of the legs, the width of the legs the bolts that holds it together.

If I am not mistaken Rohn 25 uses two different size hardware - bolts to hold it together.

Some TV towers do not - even if it has lattice - it always isn't ROHN...

http://www.rohnnet.com/rohn-25g-tower

Just as you cannot appraise a automobile or a house or a piece of property over the internet - so too you can't appraise tower.

Two rules of thumb - if the exterior is pitted - it is no good.
If the interior has rust it is no good.

Unfortunately I don't take my own advice.

The last 200' of tower I bought I paid $10 per a 10' section.

I also bought 36' of TV tower for $10.00 a section, and by the time I got it cleaned up and painted, I had $100 into each section.

That is usually the going price - unless someone wants it bad enough to pay more.

Most times most building permits will not allow you to put one up - due to building codes and covenants -and unless you are a licensed amateur radio operator and even then, 40' is probably as high as they will permit you to go - unless you live out on a farm someplace and own lot's of land.

I've been playing with several programs (tunehalf.exe, endfeed.exe,
and EZNEC).  All ask these questions:
 * Height of vertical portion of wire
 * Length of horizontal portion of wire
 * Wire diameter
 * Frequency

Endfeed.exe also asks these questions:
 * Number, length, & diameter of buried radial wires
 * Length of strap from radio to radial connection

Tunehalf also asks these questions:
 * Transmitter output impedance
 * Length * diameter of coil
 * Parallel and serial capacitance
 * Estimated ground loss resistance

Among other things, both calculate the antenna impedance.

HOW DO THEY DO THIS?  I'd like to write some programs of my own.
What is the formula or equation for estimating/calculating antenna
impedance given the above inputs?

You are far off, there is no single formula or equation.
All the advanced software programs split the antenna structure
into small parts, calculate each part separately and then
put the result together. The current in each small element
generates a field and all those split up parts interact
with the rest of the structure.
There is a name for that procedure:

http://en.wikipedia.org/wiki/Finite_element_method

In the antenna software this is called modelling.
http://www.k5sld.com/presentations/may-2009/EZNEC-basics.pdf
The antennas are put together as small pieces of wires.

Older softwares as e.g. YAGICAD use complete formulas
which give only an approximation value of the real results.
But beware: the formula for the field of a dipole is about
half a page long and is still imprecise.

w.

The Telegrapher's Equation can be used to give an *estimate* of antenna fee=
dpoint impedance for a center-fed dipole if one knows the loss factor which=
 includes radiation. The feedpoint impedance of a center-fed dipole is:

(Vfor+Vref)/(Ifor+Iref)

where all math is phasor math. The Z0 of a center-fed dipole can be *estima=
ted* from the single-wire transmission line formula. For instance, The Z0 f=
or a #14 wire horizontal at 30' above ground is very close to 600 ohms and =
the SWR on a 1/2WL dipole (including is ~20:1 in order to obtain a 50 ohm f=
eedpoint impedance (which includes end effects). For the length of time it =
takes the key-down signal to travel the length of the dipole and back to th=
e feedpoint from the open ends, the antenna exhibits a feedpoint impedance =
of approximately 600 ohms - similar to a traveling wave antenna. The loss f=
actor, including radiation "loss", can be simulated using resistance wire.

Isaac Newton is credited with saying, "If I have seen further it is by standing on the shoulders of giants."

Duplicating the work of those who have gone before may be only an entertaining exercise. (I got 1 credit in college for a Physics lab, in which I confirmed the results of experiments first performed centuries ago. Frankly, I felt a little silly doing it.)

If you're after an entertaining exercise, more power to you. (I've "created" computer programs that I knew existed.)

Whilst trying to source a "digital" TV antenna I came across some with all external surfaces plastic. One was a small yagi with all external surfaces plastic, hopefully with metal elements embedded. Another a "T" shape made out of plastic conduit with elements inside conduit.
My question is how do they work?. If they are detecting electrical fields how does increasing source impedance by 100,s of megohms improve things?. Capacitive coupling, I suppose at the frequencies involved there would be some.
If it works as well as all metal why doesn,t every one use it and stop corrosion?
Hope this is not too off topic.
Many thanks
John

I'll bite.

Look up Yagi. Mr Yagi was an English speaking Japanese graduate student who happened to study antennas in the 1930's under Professor Uda. Unfortunatly for him and history Prof. Uda did not write English, so he left documenting to the world his discoveries, and they have since been know as Yagi antennas.

His discovery was that if you take an antenna, say a dipole, and place another element in the correct position, it adds directionality to the antenna. This reduces its ability to receive signals in all directions and increases its ability to receive them in others.

(simplifed explanation follows)

Research has since shown that a slightly larger element, not connected to the antenna, acts as a reflector and increases directionality in the opposite direction, i.e. it becomes the back of the antenna.

A slightly smaller element, also not connected in the right place acts as a director, causing more restriction and more gain in its direction.

You get better results by adding directors than reflectors.

While the size of the actual antenna element effects the frequency response of the element, (wider elememnts, wider bandwidth), in most cases, it does not matter how big the reflectors and directors are, only their length and position matter.

TV antennas are unusal in that they require a very wide bandwith and other designs such as log-periodic antennas are common, but Yagi designs are used for single channel, or single band antennas.

So for example, if you wanted to receive all the stations in one direction, you would use a wideband antenna, if you wanted to receive one partictular station, a Yagi for that frequency would be smaller and cheaper.

One could make an antenna out of a piece of paper, drawing the elements on it with a conductive pen and it would work. You could figure that out, that a UHF TV signal may fit on an 8 1/2 x 11 paper, but a lower fequency one would need more space and bigger elements.

For recepetion, one only has to build an antenna that would survive its location, so for example a UHF antenna made out of a sheet of plastic, or embedded in one would make a good TV antenna near the sea shore.

It would at as a flag in the wind, so it may not be as good a choice as you think. Putting it in your attic, might be a good choice.

Lots of ham radio antennas have been made from a stick of wood as the beam (the center piece), copper tubing for the driven element (the real antenna part) and coat hanger wire for the passive elements.

Geoff.

Pardon? The coating or conduit shouldn't affect the impedance of the antenna. The radio signal should pass through the plastic and hit the metal antenna element.

Are these antennas intended for indoor use where the plastic coating is for decorative effect?
If the antennas are intended for outdoor use then substantial coating or conduiting will increase the wind loading of the antenna It also needs to be u/v stable.

Regards, Ian.

wrote:

>Whilst trying to source a "digital" TV antenna

There's no such thing as a digital antenna or HDTV antenna. There's nothing specific in the construction or design of the antenna that will make it better or worse for receiving digital or HDTV signals, as opposed to analog or digital signals. Modulation methods do not affect antenna performance (unless you're using very wide band modulation).

>I came across some with all
>external surfaces plastic. One was a small yagi with all external surfaces

URL? Picture? Vendor name? Clues? Try not to be so vague.

>My question is how do they work?.

Badly. A "small" antenna always involves some manner of compromise.
It can be bandwidth, gain, efficiency, or all of these.

>If they are detecting electrical fields
>how does increasing source impedance by 100,s of megohms improve things?.

It doesn't improve anything. Antennas much be matched to their loads.
If you're plugging this contrivance into a 75 ohm TV receiver, then
you'll need some means of matching the 100's of Mohms to 75 ohms.
Otherwise, you will have a bad case of mismatch loss. In many cases,
such mismatch loss can be tolerated, but not for VHF/UHF TV.

>Capacitive coupling, I suppose at the frequencies involved there would be
>some.

Oh? There's magic involved. No coax or twinlead cable? It just
capacitively couples the antenna to the receiver. Truly amazing.

> If it works as well as all metal why doesn,t every one use it and stop
>corrosion?

Because I have not clue what "it" is. It "it" a piece of wire shoved
into a soda straw size pipe, an aluminum tubing antenna spray painted
with plastic, or a PCV schedule 40 contrivance with a wire inside?
Please try to be more specific in your descriptions.

>Hope this is not too off topic.

It sucks. No numbers, clue clues, no specifics, nothing new, no
interest, and very little entertainment value.

>   Many thanks

One would be sufficient.

If you want to see how a program works, it's often best to go to the
source code. Most of the major programs are user friendly front ends
to the Fortran or C NEC "engine" that actually grinds the numbers.
However, there is a C version of the code available:
<http://5b4az.chronos.org.uk/pages/nec2.html>
<http://www.si-list.net/NEC_Archives/nec2c.tar.gz>
There are other source code versions that might help:
<http://www.si-list.net/swindex.html>
<http://www.qsl.net/m5aiq/nec.html>
etc...

Yes. The frequency do the work.

Rob wrote: "Apparently you have missed the interesting discussions with our
Polish
friend."

It was not the discussion. I only citate the Giants:
"In 1867 Lorenz wrote: " Ludvig Valentin Lorenz, "On the identity of the
vibrations of light with
electrical currents," Philosophical Magazine, Vol. 34, 1867, p. 287-301"

http://books.google.pl/books?id=caJdQfAKHtMC&hl=pl&pg=RA1-PA287#v=onepage&q&f=false

On p. 301 he wrote:
"The present general opinion regards light as consisting of backward and
forward motions of particles of aether."
If this were the case the electrical current would be the progressive motion
of the aether in the direction of the electrical current."

In today's words: "Light is the oscillatory flow of electrons".

So no problem for electrons to flow through the plastic if it is matched to
the frequencies.
For example,You must use the different type of glass for different wave
length.

The ice is O.K. for the RF but the water not.

> If it works as well as all metal why doesn,t every one use it and stop
> corrosion?
> Hope this is not too off topic.

It is too off the teaching programs.

You only regurgitate very old writtings, many on which have been shown to be either incomplete or outright incorrect in light of modern research.

This is usually followed by an out of context snippet from Wiki that is totally misinterpreted.

Go babble your nonsense somewhere else.

I believe he said plastic, not glass or ice.

Is your theory that if you repeat the same garbage over and over,
eventually someone will believe it?

I might as well be part of the problem, instead of the solution.
Adding to your electron belching antenna theory, such antennas should
gain and lose mass as they transmit and receive electrons. If we have
(for example), an antenna with 1A of RF current, that's equal to 1
coulomb/second. 1 coulomb is:

```
  6.24x10^18 electrons
```

which should be belching:

```
  9.11*10^-29 g/electron * 6.25*10^18 coulombs/sec
  = 5.69*10^-9 grams/sec
```

If your bogus theory is correct, you should be able to weigh your
antenna and see it loses some mass in transmit, and gains some in
receive.

Garbage in, Science out.

```

Note that it reads "... The PRESENT general OPINION ...". That was in 1867
and was an opinion so presumably it was neither a theory nor a proven fact.
We have the benefit of research made over the intervening 145 years.

It is probably unwise to quote from books / articles / papers if you do not
understand them.

The key phrase here is "usually idealized"; there are many examples of systems that don't have anything that could even remotely be considered a "ground".

> All antennas are grounded

Totally false.

You are a babbling idiot.

What does this have to do with measuring the weight change in an
antenna that allegedly is transmitting electrons? Electrons have
mass. Transmit enough of them and you'll loose mass. Receive enough
electrons, and your mythical antenna should gain mass.

Also, if the earth is absorbing your electrons, something should be
gaining a rather large positive charge as a result of the
transmission. Where is the positive charge?

While we're at it, there are many ways to detect electrons. One of
them is with a phosophor screen, that will light up when hit by
electrons. Some how, waving my HT near the phosphor screen of my
oscilloscope fails to detect your alleged electrons. Could you

perhaps offer a better way to detect the electrons allegedly radiating from an antenna?

>All antennas are grounded and you should be able to weigh the Earth because
>it gain and lose mass as they transmit and receive electrons"

I see. If I'm standing on the ground, I can't be weighed. Well, my bathroom scale is sitting on the ground and works just fine measuring my weight.

My HT antenna isn't grounded. Neither are any of the dipoles on my roof. I presume you're suggesting that they don't work.

Now, that we have the requisite science fiction out of the way, could I trouble you to answer my original question.
   Is your theory that if you repeat the same garbage over and over,
   eventually someone will believe it?

It is incorrect to say that all aerials are grounded. Dipoles, quads and
yagis aren't grounded.

Thanks. I turn on my ancient Icom IC-735, tune around 20 meters and
hear nothing. Transmit and I get infinite VSWR. Ok, something is
wrong. After 15 minutes of juggling coax cables, spinning knobs,
pushing buttons, and head banging, the light comes on in my head.
After a nasty wind storm in January, I a tree had destroyed most of my
antenna farm, which I haven't repaired. Rebuild antennas now added to
the things to do list.

Absolutely postive.

Go back to Wiki.

Reread the article from beginning to end.

Then read all the references within the article.

If by some miracle you manage to then understand what was written, you will then also realize your question is that of an ignorant idiot.

Light reading on the FT-817:
<http://www.ka7oei.com/ft817pg.shtml>

>The saving grace here is QRP with which I hope
>to get into as little trouble as possible.

As soon as the neighbors find out that you're a ham radio operator, several things will happen.
1. You will immediatly be blamed for all manner of electronic failures. Kitchen appliances, computer crashes, and prematurely dead batteries will all become your fault.
2. Neighbors will assume that you fix things for free. Training the neighbors to pay for your time will be a challenge.
3. The phone will ring at 2AM asking if you're on the air and causing reception problems with OTA TV, cable TV, satellite TV, etc.

>I'm a pretty good tech, and have fixed up and modified
>lots of stuff but now I'm going to have to do a lot of
>learning in the wild world of wire antennas and grounds.

My theory is that if it doesn't work on paper, it's not going to work when you build it. There are plenty of "standard" antennas that usually work the first time (if you follow instructions). However, you seem to be interested in designing your own. Therefore, I suggest you download the demo version of EZNEC, or the free 4NEC2, and proceed to model your prospective antenna system. When the computah says that you're close, then it's time to build it. An MFJ269 or similar antenna analyzer is handy for verifying your calculations.

Hint: One of my ham friends moved into a CC&R (covenants, conditions and restrictions) infested condo farm. No antennas of any kind. The condo council had at least one member that was certain that property values would decline if a ham was allowed to operate from the condo farm. So, I leaned a 20ft aluminum extension ladder against the house and ran a wire to the radio. It worke quite well with a tuner. The ladder was left leaning against the condo for a bit less than a year before the condo council discovered the ruse. There was a short debate. The council decided that since it had been in operation for a year without any complaints or detrimental effects, it could stay.

Luckily,in SoCal we don't contend with that very often -- Santa Ana winds in the canyons being the occasional exception. I feel for you.

Meanwhile, just hang up any old thing and agitate some 'trons. A 20m dipole at 15 feet (one end tied off to my chimney and the other end to a branch in my neighbor's macadamia nut tree) is all I have or apparently need. Yes, 1 KW into a SteppIR on a 50 foot tower is better, but at a cost of several thousand dollars per S-unit.

Really, it's all good. Maybe you heard my long-ago story about my 20m first-ever QSO with Hawaii. I got a 5-9 but the antenna was primitive: an existing 10m vertical dipole, with one end clipped to an extension ladder laying on the ground. True.

> Luckily,in SoCal we don't contend with that very often -- Santa Ana winds in the canyons being the occasional exception. I feel for you.

The winds wasn't that bad. I live in a redwood, fir, oak, and madrone forest, which blocks most of the wind. The problems are caused by falling trees and limbs. I have a fair size ding in my car hood, and had an oak tree land on my flat roof, destroying most of my antennas and trashing in a skylight. Most of the shock was absorbed by my neighbors roof.
<http://802.11junk.com/jeffl/pics/2011-12-03-Storm/>
So much for the idyllic life in the forest.

> Meanwhile, just hang up any old thing and agitate some 'trons. A 20m dipole at 15 feet (one end tied off to my chimney and the other end to a branch in my neighbor's macadamia nut tree) is all I have or apparently need. Yes, 1 KW into a SteppIR on a 50 foot tower is better, but at a cost of several thousand dollars per S-unit.

There's no way I can rotate a horizontal antenna without hitting a tree or the hillside behind my house. A tower might help, if it were 200ft high, and the swaying trees won't hit the antenna. I'm stuck with using wire antennas and verticals.

> Really, it's all good. Maybe you heard my long-ago story about my 20m first-ever QSO with Hawaii. I got a 5-9 but the antenna was primitive: an existing 10m vertical dipole, with one end clipped to an extension ladder laying on the ground. True.

Yep, RF is magic. I managed to make a QSO into a Heathkit Cantenna, but that's about the limits of my non-traditional antenna experiments. One of these days, I'm going to build an NEC2 model of an aluminum ladder and see what can be done to use it on VHF or UHF.

So, I climbed up on my roof with a balun and some wire, intending to make a dipole. Normally, this is a trivial exercise. However, there's a problem. All the labels have peeled off my multitude of coax cables. The labels were UV proof but apparently not water proof. Almost all of my coax cables came off the same roll of RG6a/u and look identical. This is going to be a problem.

I did manage to find all the parts to a Radio Shock discone antenna, which is now simulating a wet noodle on top of a 10ft 3/4" PVC pipe. That's because I can't find a single 10ft mast section that doesn't have a fatal dent or bend.

The 12ft(?) long VHF/UHF Comet fiberglass antenna survived the tree fall, but will need to come down for some cleaning. The outside is covered with green slime. Experience has shown that when the outside is covered with green slime, so is the inside.

Maybe I should give up for the day, and just clean up the workbench.

After mucho years on the air in mucho locations I can say I've been
there, done that! This is however, my first real experience using a
very limited antenna and QRP.

I have an MFJ-259B -- couldn't live without it, and with all the
stuff I gave away this was the one thing that I just couldn't part with.

Good move! I've always maintained that if you give me any old
piece of metal almost anywhere, I'd find a way to load it and get
on the air! And I've done it time and time again. I did 26 years
in the navy and moved around a lot -- quick and simple antennas
were a must! I also helped a lot of chums who moved into
condos or rest homes get on the air using similar methods.

This case now though, is the first time I ever went into a place
that seemed impervious to signals. I've often operated from
indoors with no problem, and here, the first time I flashed up the

receiver, thought it had gone dead -- that's how bad it was. The
first thing I did was checked the protective diodes on the
antenna connector and as soon as I found them OK, opened
the window and strung a short wire outside -- then everything
was 5/9 plus!

As per another sailor many years ago said, 'I have not
yet begun to fight!'

For when you transmit into it by accident...
<http://802.11junk.com/jeffl/pics/2011-12-03-Storm/>
The MJF-259B is similar to the MFJ-269B, except that it lacks the
440MHz section. It's a very handy instrument, but is rather fragile
in that the detector diodes are connected directly to the RF

connector. One blast of too much RF, too much static electricity, or even too much DC, and the diodes go poof.

>Good move! I've always maintained that if you give me any old

Welcome to the joys of modern energy efficient construction. The walls are full of aluminum foil backed insulation for both thermal and acoustic insulation. The windows are coated with Low-E Titanium Nitride IR reflective coatings (40 ohms per square), which also blocks RF. The roofing material is carbon doped (instead of asbestos) which absorbs RF. The foundation is concrete, which also absorbs RF. Meanwhile, the proliferation of microprocessors, switching power supplies, and BPL like devices, offers multiple sources of QRN. You had it easy at previous locations.

>As per another sailor many years ago said, 'I have not
>yet begun to fight!'

Fighting is easy. It's negotiation that drives me nuts.

I kind of fell behind in my knowledge of modern constuction. I lived in my house for 29-3/4 years and even though I did a lot of renos, the infrastruction remained basically the same. It is good though that they are getting smart on energy efficient construction and other things -- hopefully we will leave our kids and grandkids with a world pointed in the right direction.

>
>>As per another sailor many years ago said, 'I have not yet begun to fight!'
>
> Fighting is easy. It's negotiation that drives me nuts.

I'm on the air but not sure just how well I am getting out, I don't want to measure it, I don't even care to know since it is a whole different matter on QRP. The proof will be in the pudding -- I may have to wait for good band conditions, but the only valid means of measurement will be the number of QSO's and bands I can work.

From those lovely boxes of variable caps and assorted inductors (some roller-inductors) and a cheap 2nd hand 50ua meter I am going to build up an artificial ground which is about as simple a circuit as one can get -- the L&C in series and make a sniffer out of the meter and a diode!. I should have it all going in the next day or two -- as soon as I can get a round tooit. Yes. I admit -- I'm a master of procrastination

Well, on with the further adventures of getting on the air to the point of satisfaction. Is that a lot, I ask?

Thanks on the tips re the MFJ diodes. I'm aware of them and can test and change them if need be. So far, so good! I guess it wouldn't hurt to have some on hand -- it's pretty inevitable that with the experimentation etc, that I'll be doing some or all will get blown before you can say poof!

Do you think that if I were to ask the management here If I could have an aluminum ladder outside my second floor window -- just to easy my mind about the dangers of fire, they might agree?

Yep. It's happening, but very slowly and painfully. Ecology is expensive in the short term, but worth the cost and effort. Unfortunately, I've seen some abuse of power precipitated in the name of the environment. Like all good things, environmental correctness does attract a few flies.

>I'm on the air but not sure just how well I am getting

Oh rubbish. There are plenty of ways to test your setup that doesn't involve calling CQ and getting a subjective signal report:
1. You can login to one of the remote radios or receivers on the internet, tune to an empty frequency, and listen to yourself.
<http://beta.remotehams.com>
<http://www.dxzone.com/catalog/Internet_and_Radio/Online_Receivers/>
2. You can join one of the internet QRP clubs.
3. Weak Signal Propagation Reporter Network
<http://wsprnet.org>
4. Reverse Beacon Network:
<http://www.reversebeacon.net>
5. You can listen for beacons to check your receiver and antenna:
<http://www.ac6v.com/beacons.htm>
Our local radio club also has a remote HF station controllable over the internet (using HRD) but it's only for club members.

All an artificial ground does is tune out the ground lead inductance so that it's series resonant at the operating frequency. In effect, you're building a counterpoise. You could user your MFJ-259B or a grid dip meter to resonate the ground lead, and forget about the meter and detector. However, if you must use a meter, I suggest a thermocouple RF ammeter. Getting it to heat up the series resistor at 5 watts might be a challenge, but it can be done. Otherwise, it's a current transfomer, ferrite core, diode detector, and 50ua meter.
<http://www.w1tag.com/RFA.htm>

>I'm a master of procrastination

I have a PHD in procrastination. Never do today what you get someone else to do for you tomorrow.

>Is that a lot, I ask?

Yes, if you try to do it all at once.
No, if you take your time, grind the numbers, do a little planning, and invite all your friends to help.

>Thanks on the tips re the MFJ diodes. I'm aware
>of them and can test and change them if need be.

I could only test the diodes after they were removed. The 50 ohm resistors in the circuit prevented easy checking with an ohms guesser.

>So far, so good! I guess it wouldn't hurt to have
>some on hand -- it's pretty inevitable that with
>the experimentation etc, that I'll be doing some
>or all will get blown before you can say poof!

Yep. My experience is that certain users tend to blow up diodes no matter what they do, while others don't have any problems. I'm sure it's the user, not the analyzer. Possibly static build-up or ungrounded antennas. Dunno.

I've been fairly lucky replacing all 4 diodes without needed to calibrate the device. However, if you find the readings off after replacement, see:
<http://www.w8ji.com/mfj-259b_calibration.htm>
The procedure took me 2 full days on an MFJ-269B. It went much quicker after I read and followed the instructions.

>Do you think that if I were to ask the management
>here If I could have an aluminum ladder outside my
>second floor window -- just to easy my mind about
>the dangers of fire, they might agree?

No. Someone will probably try to steal the ladder. 20ft ladders are not cheap. I ran two u-bolts through the ladder base, and permanently attached the u-bolts to two foundation blocks with half a bag of concrete mix in the hole. Various attempts were made to steal it, but nobody got very far with 30 kg of buried excess weight attached. The connecting antenna wire also acts as a capacitive alarm when the HF radio is not being used. All this was only possible because each condo had its own private back yard.

Another problem with a 2nd floor ladder is that you will be feeding the ladder from the top, rather than from the bottom. That will possibly work, but probably not as good as feeding the ladder from the bottom.

I won't care about subjective reports -- I'll be happy if
my few paltry watts that do escape the antenna get me
any kind of response. I am aware of the remote
receivers but I don't want to get so busy using other
things that I won't have time on the air making
plain good old fashioned QSOs. I will have a peek
at the internet QRP clubs as long as I don't lose
on air time going to meetings -- even on-air!

I considered that. I already have a group of radials
of various lengths on the floor -- I tied them together
with plastic ties for neatness, but with a ground tuner
I only need one which I plan to lay out along the edge
of the carpet -- that should make a neater job and if
I can tuck most of it under the baseboards it will not
frighten the houskeeper.

However, if you must use a meter, I suggest a

A simple diode detector may be enough, but if necessary
I'll have to line up ferrite core and get complicated.
>
>>I'm a master of procrastination
>

I was always good at procrastination however I did not consider
the part of having someone else do the work -- that's probably
why you have the PhD and I don't!!
>

That's the nice thing about being a retired senior -- I can take
all the time I want, and as you've seen in this thread, I'm
doing a lot of planning, and if necessary there I've got
lots of ham chums who will be anxious to lend a hand just
to get in here and see what I'm up to.
>
>>Thanks on the tips re the MFJ diodes. I'm aware

I have the W8JI procedure tucked away in a safe
place on my computer where I may never find it again,
Thank heaven for good search tools.
>

I never considered that -- oh well, it should only take a jiffy
to pop the diodes out although there is always Murphy to
take into account.

Now there's a very unhamlike suggestion -- wouldn't stopping
to read and follow the instructions severely slow down the
calibration procedure?
>

I've considered all the security precautions you took with the ladder.
At the moment I'm considering how to rotate it, and
wondering if I couldn't use a wooden ladder with lots
of wire stapled to it in a multiband Hentenna configuration!
I guess I may have to rethink it and take it one step at
a time! Now, I have to consider which rotor. Do you by
chance know offhand the wind load of a 20 ft Al ladder?
How about a folding ladder for the sake of extra length?
>

I'll use double sideband so that it won't matter which end of
the ladder I feed it from!
>
Cheers, this is fun!

Umm... the diodes don't quite pop out in a jiffy. You must first tear
apart the instrument just to get to the diodes. They're tiny little
devils, best handled with stainless SMD tweezers.
<http://802.11junk.com/jeffl/crud/mfj-269b-diodes.jpg>
They're the 4 black things labeled "COB". If you order some from
Digikey or Mouser, be sure to get plenty of spares. I dropped two on
my workbench, where they promptly disappeared.

If you can remember parts of the file name or folder, it will find it
instantly.

I consider reading instructions a sign of weakness, especially when
customers are watching.  When they see me reading the docs, they
usually ask if I know what I'm doing, or if I had done this before. In
order to maintain my image, I try not to be seen reading the docs.

However, I do read the instructions..... after I'm done, and only to
see if I missed anything.  On the MFJ-269B calibration, and after
starting over for the 3rd or 4th time, I decided that it might be
useful to just do it right, reading from beginning to end.

>At the moment I'm considering how to rotate it, and

>I guess I may have to rethink it and take it one step at
```

>a time! Now, I have to consider which rotor. Do you by
>chance know offhand the wind load of a 20 ft Al ladder?

No, but I could probably calculate the wind load if I had the dimensions. Ice load will probably be the worst case. However, I don't think a rotatable ladder would be a good or useful idea. The ladder is mostly vertical, and rotation of a vertical doesn't do anything useful. I suggest you leave it leaning against the building and live with whatever that produces.

Incidentally, if there's anyone living directly below you, they may object to having the ladder block their view. My friend's ladder antenna was possible because his condo was a townhouse arrangement, where he owned both the lower and upper windows.

>How about a folding ladder for the sake of extra length?

The 20ft ladder I used was a 2 section telescoping ladder. I had the not so bright idea of changing the length in order to tune the antenna to something near 1/4 wavelength. I also experimented with an insulating sleeve between the two sections in an attempt to make a vertical dipole. Both proved of dubious value as the best results were from using the full length ladder and an antenna tuner.

I'm not sure what a folding ladder will do except to add weight and attract unwanted attention. I just gave away two steel folding ladders. They weighed far too much but were admittedly quite useful.

>I'll use double sideband so that it won't matter which end of
>the ladder I feed it from!

Be sure to tilt your radio vertically to match the antenna polarization.

>Cheers, this is fun!

If it were easy, it would not be fun.

```

> Umm... the diodes don't quite pop out in a jiffy. You must first tear apart the instrument just to get to the diodes. They're tiny little devils, best handled with stainless SMD tweezers.
> <http://802.11junk.com/jeffl/crud/mfj-269b-diodes.jpg>
> They're the 4 black things labeled "COB". If you order some from Digikey or Mouser, be sure to get plenty of spares. I dropped two on my workbench, where they promptly disappeared.

After I retired from the Navy I worked for Sony as a tech for 14 years and became pretty handy with SMD. When I retired from Sony I kept my tools which included a headband magnifier and a few different tweezers only one of which I consistently used. I do recall losing one or two of the smaller SMD components but I eventually learned to take precautions to avoid doing so..

With respect to taking things apart and then getting them back together again I have to brag about my abilities. When

I had my first interview with Sony the asked me how much
of the work I considered electronic and how much was
mechanical. I estimated 90 percent mechanical (getting
the old part out and putting the new part in and then
the unit back together). I know now that it is more like
99.9%.

Oh well, I guess I'll just have to try and not blow
the diodes even though we both believe it will be
inevitable!

Scale back a little....
I put up a fan inverted -V cut for 80-40-30 a while back just to test.
I use a tuner, as long as the transmitter likes it, I like it.
I hardly ever use 80m, no particular reason, I just don't.
The ends droop to whatever was convenient. I did not bother to consider anything permanent. Most of the ends are secured at the perimeter of the yard via nylon braided line attached to military surplus fiber glass mast sections leaning into convenient trees. I only worried about keeping the ends high enough to avoid contact with people, tractors and deer in the yard.

It seems to work well on all bands I have tried. Although I prefer my manual MFJ tuner, the internal tuner in my TenTec Jupiter seems to do OK. I am not a contester, a DX hound or a perfectionist but I do like to spend a little time on the air.

I would make up a coax balun of about 8 turns of coax on a milk jug with connectors appropriate to the roof connections. The Dollar Store here sells black vinyl tape for about $1 for two rolls so wrap the balun up well enough to not become a future problem. Pick any cable handy on the roof, assuming that they all go to the shack. When you get to the shack, use the cable that has signals on it.

I don't know which direction is favored on any band nor do I really have any idea which elements are active under any given circumstance.

It will keep you on the air and give you time to decide where you want to go from here with out undue pressure!

I worked for Sony/Superscope in Sunland-Tujunga California for a short while in the mid 1960's. Too far to drive from where I was living and going to skool.

>When I retired from Sony
>I kept my tools which included a headband magnifier and a few

Does your former boss know about this? Is there a reward for turning you in? If you're going to pilfer the tools, at least take something expensive.

I left one company with my junk parts box, my collection of component samples, a DVM, and my favorite screwdriver. I probably could have taken a load of test equipment, as nobody seemed to care. I figured the dumpster would be full of junk after the layoff/purge. I was right and collected quite a pile of goodies from the dumpster. I also suspected that my project notes would be thrown away, so I grabbed those. Many years later, the company raised one project from the dead and called asking if I had any history on the project. Like a fool, I just gave it to them, instead of demanding payment.

Like all products, my ancient products eventually hit the surplus market. Like all good surplus equipment, there were no manuals to be found. So, like a complete fool, I scanned the manuals and posted them to my web pile. I now waste far too much time answering questions and helping with repairs. Lesson learned: Products tend to rise from the dead and will haunt you like zombies.

>I do
>recall losing one or two of the smaller SMD components but
>I eventually learned to take precautions to avoid doing so..

My standard precaution is to buy extra parts. The parts are cheap. My time is not. I use metal egg trays for parts storage. However, I also tend to tip those over or bury them in junk. My latest trick is using semi-sticky window shelf paper to hold parts. That works great after I remove the flies, bugs, and glue eating banana slugs.

>With respect to taking things apart and then getting them
>back together again I have to brag about my abilities. When
>I had my first interview with Sony the asked me how much

Agreed. When I started in engineering, it was 99.9% engineering and 0.01% politics. 15 years or so later, it was 99.9% politics and 0.01% engineering. Productivity was about the same in both cases. Now that I'm officially in the repair biz, my guess is about 33% repair, 33% paper shuffling, and 33% customer ego support.

One nice thing about ham radio is that if I announce that I'm working on a project, and I procrastinate enough, then one of the local hams will eventually do it for me. See Tom Sawyer white washing a fence for details on how it works.

>Oh well, I guess I'll just have to try and not blow
>the diodes even though we both believe it will be
>inevitable!

Not really. As I previously ranted, only certain people seem to blow up the diodes. If you haven't blown any diodes by now, you're probably safe. Just don't loan it to any of your friends, especially on Field Day[1]. What seems to kill the analyzers is the act of plugging in and unplugging a PL-259 to the unit. The PL-259 is unique in that the center pin makes contact before the ground. This is what's commonly known as a lousy idea. If you've built up a static charge with your clothes and shoes, and are holding the shield, you'll discharge yourself through the center pin and directly into the diodes. That's my guess(tm) as to what's happening. I now make it a habit of touching the center pin to case ground, before plugging in. No clue if it helps, but it seems like a good idea. The N connector on the MFJ-269B should not have this problem, but they seem to blow up anyway, probably due to a different failure mechanism.

>Irv VE6BP

[1] Hint: Measure the DC voltage on the traditional Field Day
balloon supported long wire antenna, especially if there's some wind.
If the DVM doesn't explode, you're still not safe.

I actually asked permission. It is because I have always been
fair and honest that I am known as 'Fairly Honest Irv'.
I couldn't take any test equipment or the Fluke 77, but
I luckily picked one up for $25 at a flea market.

I use the sticky tape method too! Now If I could just find where
it put it!

> for details on how it works.

That's pretty common here in town. If an antenna is being
raised, even digging the hole for a tower, there is usually a
good turnout of the younger more able hams. Some say
that hams aren't like they used to be, but for the most part
I find them a good crowd.

>

> anyway, probably due to a different failure mechanism.

I wouldn't even loan it to my mother, had she been a ham,
but I've carried it to a few hams but did the testing myself.
It cost more than most of my rigs!

Irv VE6BP

> balloon supported long wire antenna, especially if there's some wind.
> If the DVM doesn't explode, you're still not safe.

When I was still a pretty green ham, I heard a snapping noise
one night -- found it coming from the tuner! Wouldn't touch it
till it stopped! I eventually learned about wind static.

I got plonked by a famous ham when he challenged me to tell the
difference between a 50 ohm dipole and a 50 ohm dummy load if I
couldn't see what was attached to the transmission line. I answered,

"Field Strength Meter?", and he plonked me.:)

Reminiscent of an old story about how to establish
the height of a tall building with a barometer: Go to
the super and offer the barometer to him if he tells
you how tall the building is.

Also, drop it from the building's roof and time the fall.

d = 1/2 (g (t-squared)) Can also use a watermelon.

The "real" answer, involving atmospheric pressure
difference, is no fun at all.

"Sal"

Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team had decided to consider |
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. After a successful trial |
period (90 days, through early July 2009), we decided to adopt this |
change permanently. |

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded

```
name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

If caught, I usually ask for forgiveness. It's easier than asking for permission. I've gone by various names, none of which involve being honest.

>I couldn't take any test equipment or the Fluke 77, but

>I find them a good crowd.

The local help is mixed. In general, a work crew can be organized, but it's not like it was 20-30 years ago. The problem is that the bulk of the ham population is aging and thus unable to do many of the dumb and dangerous things that are considered normal for younger hams. I gave up tower climbing at age=50 and steep roof climbing at age=60. If I can't find a way to not trip over the coax cables and walk into the guy wires on my roof, I may need to give up flat roofs.

When dealing with 100ft+ trees, I hire a professional tree climber. I also have him prune the tree at the same time. I have two stainless sailing blocks (pulleys) up in the trees for raising wire antennas. Unfortunately, the rope used to raise the antenna rotted and broke. If I can find an excuse, I'll hire a tree climber to replace the ropes.

>I wouldn't even loan it to my mother, had she been a ham,
>but I've carried it to a few hams but did the testing myself.
>It cost more than most of my rigs!

The MFJ-259B sells for $240 from various dealers. Your FT-817ND sells new for about $600. Either you overpaid, or you're getting a sweet deal on the radios.

If it's anywhere near a 1/2 wave dipole, a fan dipole shouldn't need a tuner. I've built two fan dipoles over the years. Since everything affects everything else, I spent far too much time adjusting the wire lengths. I eventually settled on a trapped dipole, which was easier and worked the first time. Either antenna would work for me except for the length. I don't have the room for a proper 80 meter dipole. For the immediate problem, I'll be happy if I can get on 20 meters (PSK31) and 10 meters (radio club net).

>It seems to work well on all bands I have tried. Although I prefer my

>OK.

Antenna tuners can be quite lossy. Have fun with this Java app:
<http://fermi.la.asu.edu/w9cf/tuner/tuner.html>

Do you have a field strength meter? Find a location in the pattern and as far away as practical. View the meter from your operating position using binoculars or a telescope. Try your fan dipole directly to the 50 ohm output of your transmitter. Hopefully, the VSWR will be less than what it takes to trip the VSWR protection circuitry. Now, install the antenna tuner and try again, keeping the RF power at the same level. If you have problems leveling the RF power, use an AC powermeter, such as a Kill-a-Watt, to measure the AC input power consumption. When I did the same test, the antenna tuner always had noticeably less TX signal strength.

>I am not a contester, a DX hound or a perfectionist but I do like

I spend more time inside the radios than in front of them.

>It will keep you on the air and give you time to decide where you want
>to go from here with out undue pressure!

The answer for me was supplied by outside influences. A mess of work
arrived at my shop, so I'll be too busy to do antennas for a while.

FYI I spent an afternoon with EZNEC exploring fan dipoles.

What I found was the farther apart the wires, the less the interaction, which is what one would expect from common sense.

From my limited runs it appears that somewhere around 20 degrees is about where the minimum separation needs to be for practical length adjustments.

At angles less than that be prepared to spend a lot of time pruning.

It doesn't matter if the wires are separated vertically or horizontally other than horizontal separatation means you need lots of support points.

If the bands are too close together, i.e. 20-17, 17-15, 12-10, you can never get both bands to "work", i.e. a decent match.

That appears to be also true for trap antennas from some limited EZNEC modeling.

Of course, there is always the alternative of throwing technology and money at the problem and just put up whatever wire you can and put an autotuner up.

The FT-817ND is my first store bought rig.  Prior to my downfall
from good health, I always had either surplus which I'd converted,
or old rigs off the local Swap 'N Shops which needed repair.  As
much as I say I'm going QRP, if I can pick up an old Kenwood
tube-job I think I'll give it a go!  Unless I have a number of knobs
and switches to play with I sense a loss of control running the
new stuff.

 A TS-820 or 830 would be great -- I had an
820 that really performed for me for a long time -- I gave it
away when I went in the hospital.  I repaired a lot of Kenwoods
Swans and Yaesu's (not to mention other makes) for old-timers
and really enjoyed fixing them.  I repaired a lot of the
newer solid-state rigs as well, but preferred the old
classics. I have a lead on the 820 I gave away, and may
end up getting it back.  When I got it, it didn't have the
DC converter or the digital display but I managed to find
them on a cannibalized unit. It even had the
CW filter..  The only other thing I'd need would be
a keyer for a beautiful mint Bencher key I picked up
from an estate sale.  The beauty of the Kenwoods is
that as long as 6146s and 12BY7s are available I know
I can keep them running.

<snip>

I have antenna challenged yard, with no available supports for horizontals. So I've been experimenting with vertical radiators mounted on a 12 by 30 foot metal patio cover.

Initially, I used a CB whip, fed with RG-58 to a tuner in the shack, quite successfully on 24 and 28 MHz. After a few more tests, (and more tests are planned) I settled on a 14 foot radiator that works well on 20-10 meters. It did a good job on all those bands during the recent DX contests, but obviously won't bust a full fledged pileup without some operational cunning.

The antenna is fed with 25 feet of RG-8 to an RF ammeter in the shack and on to a tuner. The ammeter is used to get the most current with various tuner settings/configurations, but without changing anything from the ammeter to the antenna.

So, a tuner in the shack feeding a single dipole might fit your band coverage and real estate requirements. Play around a bit with EZNEC and try a few things.

I've got 12 and 10 working fine together, seperated by about 8" giving a
decent match. It also works fine on 15 although no wires for 15, but a short
coax (20') to an ATU. It has a "pawsey stub" balun cut for about 17m (modeled
with NEC for best match with fan dipoles for all bands 20 -10, but I haven't
as yet got round to dipoles for 15 and below).

I was refering to the case where there is nothing to adjust the match and
getting something under 3:1 at the end of the feed line.

Given an ATU, you can usually match anything and there is no need for the
physical complexity of a fan dipole.

It was well within 1.5:1 within (part of) 10 and 12m bands.

>

Very true The ATU is  only used for 15,17 and 20, but my (larger) doublet
with tuned feeders is better for 20 and 17, and about the same for 15.

I'm currently debating whether to add additional dipoles to the fan or
replace it with a smaller doublet (about a half wave on 20), which would be
about half the size of the existing doublet.

I may end up trying both, I doubt if there will be much difference apart from
a slight change in directivity.

I was refering to the case where there is nothing to adjust the match and
getting something under 3:1 at the end of the feed line.
#
Given an ATU, you can usually match anything and there is no need for the
physical complexity of a fan dipole.

An open wire fed dipole would give pretty good performance. But, feeding
such an antenna with RG-8 and living with a high VSWR (maybe up to 10:1)
shouldn't be discarded.

A dipole of about 18 feet would cover 24 and 28 MHz with about 5:1
VSWR....not bad.

After spending several hours with EZNEC trying to get that combination under 5:1 with no success, I find that hard to believe unless something in the system is really lossy (like the feedline) and masking the SWR or the length of the feedline just happens to be at a length to help the match.

My transmitter gives up at about 5:1.

Your milage (and transmitter) may vary.

# My transmitter gives up at about 5:1.

# Your milage (and transmitter) may vary.

Yes.  My Yaesu ATU gives up at 5:1, so I have been using a more robust
homebrew tuner.

A VSWR of up to say 10:1 (perhaps 15:1) shouldn't be a deal killer, if you
can match the coax and are willing to accept 2-3 dB of loss.  This opens up
a lot of antenna possibilities that might be otherwise discarded.

Well, my trap inverted vee for 40-30-20-15-10 has a SWR of less than 2:1
where all my interests lie, and less than 1.5:1 on most bands.

Then there is the vertical that currently covers 160-10 at less than 1.3:1
on all frequencies for the days when I want to do something different.

It started out as about 33 feet of tubing for 40.

Wanting more, I built an enclosure containing a pair of relays and loading
coils so it was less than 2:1 on the areas of interest on 160 and 80.

Wanting more, I mounted a SGC autotuner at the base so it is always 1.3:1
or less on all bands.

EZNEC analysis says the lobes are low, and actually have some low angle
gain on 15 and 17, until I get to 12 and 10, where the lobes start pointing
to the sky.

The next modification will likely be finding a 10 M trap at a swap meet
and installing it at about 5/8 wavelengths to push the 10 M lobe down.

I can live without perfection on 12.

Out in the YARD, on top of 30' of 1.25 inch semi rigid conduit I have a Solorcon A99 that looked like a fussy Popsicle stick that a friend of mine gave to me that I painted with some dollar general store paint - which tunes up with the internal antenna tuner in my Kenwood TS 590S - which is below 2:1 on 10 / 12 / 15 / and 17 even without the tuner - as long as you stay within the bands - 28.300 - 28.500 etc.... And will tune up beyond that - 26.950 / 29.690 MHz with the internal tuner...

I had a 10-20 fan dipole laying on a roof for a while. Matched OK after a
bit of pruning but I abandoned it when I found both bands were better with
antennas that were clear of the roof.

I wonder something (and I suppose I'll have to try it, now) : Say I had a 20m horizontal dipole up at 30 feet, could I feed it through a coax that had a Tee-connector located 22 feet up and simultaneously feed a 15m antenna from that Tee-connector?

Just as they would be in parallel as a true fan dipole with a common feed point, so also would they be in parallel -- just not sharing a common feed point.

Normally I avoid Tee-connectors because they introduce the Evil Mismatch but this time ...

I can see one problem already; some of the 15m energy that divides at the Tee-connector would go up to the 20m antenna and be partially radiated and partially reflected. Standing waves. The coax length would alter the effect.

> FYI I spent an afternoon with EZNEC exploring fan dipoles.

I've used those for many years.. Probably my #1 most used antenna.
I have them here at the house, and also up in the country at
the recreational living center.

>
> What I found was the farther apart the wires, the less the interaction,
> which is what one would expect from common sense.

Yep, and if at right angles, there is virtually no interaction at all.
I've had cases with dipoles at right angles where one leg broke off,
and the SWR for the unbroken intact dipole did not change.

>
> From my limited runs it appears that somewhere around 20 degrees is about
> where the minimum separation needs to be for practical length adjustments.
>
> At angles less than that be prepared to spend a lot of time pruning.

yep, and it can get weird.. IE: the tuning appears to work backwards
from the norm.. It will almost always be one of the higher bands that
is effected. Rarely the lower band. And in many cases, you will end
up adding wire to the higher band dipole, to come up the band. A bit
peculiar, but I've seen it many times.

>
> It doesn't matter if the wires are separated vertically or horizontally

Not sure if I agree with that. I would think it *should* work if the
two dipoles are at right angles. And likely good nuff for gov work,
even if at a closer angle.
But it's not something I've really tested, as I generally don't worry
about the higher bands, and tend to load the lower band wires on the
higher bands. I rarely ever string dipoles for 17,15,12,or 10..
The 40 meter legs pretty much cover 15m for instance.. I've never added
15m legs, as I always have 40 legs.. I have often added 20m legs though,
as the 40m as a half wave on 20 is the pits when coax fed.. :(

>

> modeling.
>

> Of course, there is always the alternative of throwing technology and
> money at the problem and just put up whatever wire you can and put an
> autotuner up.

Yep.. But I've always like the parallel fed dipoles.
It's almost a perfect system. When tuned and operated correctly, the dipoles function pretty much the same as single band dipoles, with no tuner needed, and pretty much the same efficiency as a single band dipole fed with coax. For multi band use, it's more efficient than most any other scheme I can think of as far as the bands that have dipoles, or have a good match for other reasons. IE: 3/4 wave resonance.
The one here at the house is 80/40/20. The one up in the country is 80 and 40. I did also have 160m legs on that one at one time, but a storm whacked it out, and when I rebuilt it, I didn't bother with the 160m legs.
If I want to use a higher band, I use a tuner and accept the small loss.. I actually don't get on the higher bands much.. I'm on 40 in the day, and 80 at night most all of the time. Also 160 at night if I have it, but that is a bit seasonal.. You won't see me on 160 much in the summer.. So much noise, you really need an amp, and none of the amps I have work 160m.

EZNEC lacks an optimiser. Try 4NEC2 and let the optimiser tweak the

wire lengths for best VWSR in the various bands.
<http://www.youtube.com/watch?v=kYy6Yur127A> 25min
The bad news is that since the fan dipole works on several bands, the optimizer has to be run individually for each band. Fortunately, it is easy to limit the parameters that it changes to just the wire length for that band in question. I'm tempted to build an NEC2 model and see what happens. Maybe this weekend.

I blundered across this article on fan dipole construction:
<http://www.hamuniverse.com/multidipole.html>
<http://sstowers.com/aa4cv/>
If I can find a long straight location, that doesn't come too close to a tree, I might try a fan dipole again.

Well I modelled it and matched it fine on the two bands The ends of the feeder are about 4" apart and effectively the inner ends of the longer dipole are an 8" length of 600 ohm line, so that length comes off the 12m dipole elements. I couldn't get it to match with it as a genuine fan (inner ends paralelled) with any small spacing at the ends of the dipoles, so I made them about 8" apart.

Then they matched up nicely. The feeder is short, and low loss, as seen by the out of band (mis)match.

The trick is to make the dipoles far enough seperated so as to be seen by the feeder as seperate elements. This lost me much time.

Why not put a quarter wave stub for 10metres about half wave down from the
top to make it radiate as two half waves in phase on 10? That would also
guive a little loading on the more LF bands increasing efficency slightly.
I'm not sure without checking what the effect on the bands below 20 would be.

I'd like to see the model.

Mostly because of the mechanical complexity of doing that and the winds
here can exceed 60 MPH.

Inserting a trap is much simpler and catches less wind.

Went to the 'preview' of our church rummage sale last night (church members get first crack at the stuff) looking for any interesting boks; inestead walked out with a RS PRO-37 handheld scanner complete with fresh batteies and in perfect working condition for..are y'all sitting down?

$2.00

Top that for a find!

If I were going to do that, I would use ladder line between the elements
and connect the coax to the bottom.

It would be easy to model this with EZNEC, even the free demo version, so
I would do that first.

> No. The counterpiose is the ground.

How can a counterpoise or chassis serve as an infinite source of
electrons? When your theory would be right, the counterpoise would
get charged just like the antenna.   In reality this does not happen.

The counterpoise only serves as a place to dump AC current (the output
of the transmitter) during the cycle of radio frequency output. It is
not (and does not need to be) an infinite source of electrons because
elecrtrons are not emitted by the antenna.

You see that you can make spelling errors yourself.
Maybe you should consider that when making fun of other people's
spelling errors.

Hello Irv,

On 2012-04-23, Irv Finkleman <finkirv@shaw.ca> wrote:
> 1. Is there wire with camoflage insulation? (just kidding!)
> I plan on using wire with beige or tan colored insulation. I

I do a fair amount of camping with portable operations and have an 80m loop and end-fed zepp at the house in a residential area with no restrictions. Actually, the black or copper wire (when it starts turning from shiny) is the less visible of all, either against sky or trees. My ef zepp is white with blue stripes and it actually glistens at certain light angles. You actually have to look to find the loop in the yard and it is 294 ft long, made of #16 gauge copper clad.

> a 1/4 inch hole in the aluminum window frame. I was going

> through the hole to prevent any problems?

With a 1/4 inch hole, actually might be less, you could run a very short piece (a few inches/cm) of r8x, r59, r58, or any of the smaller coax and simply trim off the shield at the end and use the middle conductor for the wire. Also, small rubber, teflon, or plastic tubing such as used in model airplanes might work.

I use parallel pieces of coax with shields soldered together and connect my open wire feed to the center conductors to get under my metal framed window. Actually have a strip of wood with holes for this and close the window down on that strip of wood. Of course in the winter up in AB you have to be more careful with cold air than we do in Louisiana. hi

Will listen for you on the air. Good luck.

It's a new hole -- two days old now though. I am using an MFJ-1623 tuner which also includes tuning for the counterpoise ground which I'll be using.

The wire will be enough to hold one small bird -- if necessary I can always rebuild with heavier wire (the MKII version I mentioned before)!

I checked carefully before I drilled and missed the glass entirely which is unusual because Murphy lives with me! I've never seen him, but his influence is always around!

The magnetic loop would not be using the window frame -- I have some 1/2 inch flexible copper tubing which I brought from my condo (which will officially be off my books at noon today!)

Last week we had a flea market in Calgary. Having given away all my precious ham radio parts (aka junk) I was in dire need of a roller inductor and a variable capacitor or two to build (if necessary) an artificial ground, or a matching device of some sort for whatever purpose I might dream up.

I walked into the market, paid my admission, and the first thing I saw was a box (about 4 cu ft) of variable caps of assorted shapes and sizes. I bent down to have a closer look since I could hardly believe my eyes, and asked the seller 'How Much?' At the same time, I noticed another box of the same size full of assorted inductors, some roller inductors, some coil forms, some coil stock and such. It was like a dream come true. The seller responded '20 bucks for the whole box' and I asked 'How about 20 bucks for both boxes' and he accepted! Talk about a lucky find -- some of that stuff is hard to find nowadays, and to purchase would cost a fortune. I have both boxes in the trunk of my car as there is little room in my suite to allow me to start collecting parts aka junk! I've brought the cream of the crop up to my suite and have cleaned them off using an electric toothbrush and a mildly abrasive cleaner -- they look like new. I now have sufficient L and C, both fixed and variable, or every sort and description to keep me happy for a long while. The rest I will store in my brother's garage until the next flea market where I intend to recoup my $20 bucks plus the admission price!

I've tested the MFJ-1623 and it will work 80 thru 10M with the wire -- the wire is basically the same as the 12 foot whip only longer but thinner. If it doesn't, I have another MFJ-949E which I got as junk because the coil switch was burned (I replaced it in an hour with a new single pole 12 position) and it's been tested and used by a friend of mine for the last couple years. If one or the other works or doesn't, I've got all that LC stuff from the flea market so if necessary I can put together enough to load a wet noodle.

I did load a wet noodle once, and worked from Penhold AB to Red Deer AB (about 10 miles) just to show it could be done! I love antennas.

Does anyone recall reading a book on antennas that had a Chapter subtitle saying 'Antennas are Funny People!'? I'd love to find the book again.

My carpeting is wall to wall, so the chicken wire ground would have to be on top of the carpet. I'm sure though, that if anyone asked, I would simply explain 'I'm a Ham' and they would shake their heads understandingly and not ask any more foolish questions!

One way or the other, with the planned setup, I intend to get some signals out -- come hell or high water. I don't give up on my hobby after all these years, and I've helped many a ham get on the air under worse (but not much worse) circumstances.

Gotta get downstairs and vote -- we are having our provincial election today!

This first antenna here is going to be quick and simple with Tan
colored wire. If that doesn't work, the MKII may incorporate
your suggestion!

I considered the coax feed through but would prefer it all be one piece of
wire from the tuner to the end. Thanks for the suggestion though.

When I had my house, I had so many holes drilled in my basement
window that the frame looked like a strainer. I ran open wire and used
the same arrangement for my open wire feeder -- I've always liked
open wire -- it permitted so much more than a coax fed antenna
system.

Thanks again for your assistance!

wrote:

>The wire will be enough to hold one small bird -- if necessary

Attach a spring to the end of the wire. That will take up the slack and help absorb the impact of the bird when landing on the wire. If you don't mind reinstalling the wire occasionally, attach a thin sewing thread on the end of the wire. When the bird lands, the thread will break, not the wire.

>I checked carefully before I drilled and missed the glass

You were lucky. Try not to rely on luck.

>I've tested the MFJ-1623 and it will work 80 thru
>10M with the wire -- the wire is basically the same as
>the 12 foot whip only longer but thinner.

Yep. I would expect it to work with the 12ft antenna it was designed for. However, you were suggesting a 50ft long antenna (with a tree in the middle), which might not work.

>If it doesn't,
>I have another MFJ-949E

<http://www.mfjenterprises.com/Product.php?productid=MFJ-949E>
That's much better.

>My carpeting is wall to wall, so the chicken wire
>ground would have to be on top of the carpet.

I've snuck flat CAT5 cable under wall to wall carpet for wiring a LAN (for internet connectivity). A steel wire snake, a carpet kicker, and an assistant, was all that was needed. Could could do the same with thin copper wire and never see a lump.

>I'm
>sure though, that if anyone asked, I would simply

>heads understandingly and not ask any more
>foolish questions!

Hint: It's much easier to ruin your reputation than it is to improve it. Methinks it best to look and act normal for a few weeks, and then surprise the neighbors, than to do the reverse.

They work like the receiving antenna of the cristal radio. Electrons from
the air go into metal.

Counterpoise is exactly like underground "ground". But if the soil is dry
sand or the rock there no free electrons. It is better to place the
conductors in the air.

Where the voltage is there must be the electron emission.

Experiments with the photoelectric effect shown that no current below 10V.
But it apply to the flat cathode.
If the cathode is a wire the voltage is lower.

And what is with your antenna in sunny day?
S*

That is not what an antenne does.

But they are not connected to a source of free electrons, so if those
would be required they would be depleted pretty quickly.

Even if there are a couple of electrons that jump off the antenna,
it is not going to cause a measurable effect. You need more than a
couple of electrons to have a measurable current, and it is not going
to happen at those voltages and daylight conditions.

Calgary, is that right? Do you need to allow for snow, ice and wind in
designing your antenna?

I have had good luck while camping, with transparent fishing line at the
end of antenna wire. It has some stretch, is easy to tie to tree limbs,
etc. And a spool will last forever.

Unless you have other ideas for the window hole, put the wire through and use a hot glue gun to seal the hole. If you can reach both sides of the hole, do the same on the outside. RTV also works.

Good luck. Paul, KD7HB

Thanks Paul,
I never thought of it, but some monofilament (I'm a sport fisherman) will fill the bill. Until now I've always used parachute cord but don't have any anymore. I plan on sealing the hole at both ends with RTV. Hopefully the wire I use will stand up to the harsh Alberta winters, all my antennas have so far, but if need be I can readily replace the wire with very little effort. According to my calculations, which include Murphy's Laws, the antenna should stay up until minus 40 degrees, a windstorm, and blowing snow occurs -- and according to Murphy it will all happen in the middle of a QSO with some extremely rare DX!

Personally, I have always found Murphy to have been somewhat of an optimist!

Thanks again for the suggestion,

Irv VE6BP

The selfcapacitance of an antenna is very small. You need a couple of
electrons to have a measurable static voltage.
For this reason the earth/chassis/counterpoise is necessary.

Hello Szczepan.
A dipole aerial doesn't need a counterpoise nor does it need any connection to earth/ground/counterpoise.

I've kept quiet during the discussion because I don't think of my radio and aerial in terms of sub-atomic particles. For me, resonance, impendance and SWR are more significant.

Have you considered taking your theories / discussions / cutting-and-pastings about sub-atomic particles and other kindred items to one of the physics newsgroups such as:
   alt.sci.amateur
   alt.sci.physics
   sci.physics
I'd expect that you will find lots of people with whom you can discuss the behaviour of sub-atomic particles.

Kindest regards, Ian.

Is it your transmitter:
http://rf.circuitlab.org/2011/06/80mw-fm-transmitter-with-dipole-antenna.html
?
>

Your dipole are exactly like the two Kundt's tube. There are "resonance,
impendance and  SWR". To demonstrate of the SWR the tube end must be porous.
 Air molecules work like the electrons.
```

Electrons are the subatomic particles.
Radio is the only field where "plumber analogy" is totaly inadequate.

Kindest regards,
S*

Definitely not. That's a full wave aerial. It's an FM transmitter. I use SSB and CW.

> Your dipole are exactly like the two Kundt's tube. There are "resonance,

The ends of my aerials are not porous.
According to Wikipedia, Kundt's tubes are used to measure the speed of sound in a gas or solid rod.

Have you considered taking your theories / discussions /
cutting-and-pastings about sub-atomic particles and other kindred items to
one of the physics newsgroups such as:
 alt.sci.amateur
 alt.sci.physics
   sci.physics
I'd expect that you will find lots of people with whom you can discuss the behaviour of sub-atomic particles.

I am using a random wire antenna which runs outdoors through a hole in a window frame.

I do not have access to any good RF grounding system and plan to use an indoor counterpoise wire from the ground connection on the tuner (MFJ-949E). I have a nice role of #18 wire, the end is connected to the tuner, and it is my intention to unroll it along the floor through my suite until such time as it is properly tuned.

MY QUESTION IS - How can I tell when I have unrolled the right amount of wire for the frequency in use. I know it will not be 1/4 wave, and that it should be less. From what I understand, when it is adjusted properly I should not have any hot RF burning my lips from the mike. Checking it with my lips is not what I call a desireable means of testing, and being single I cannot call my wife to test it for me. I'd like to find a better way and hence my questions.

I believe (according to what theory I have learned) that the tuner chassis would be hot with RF, with the amount of RF becoming less and less as the counterpoise wire approaches the proper length. If this is true would a simple RF sniffer tell me? I can rig one up fairly easily.

OR - What would I be looking for using my MFJ-259B SWR Analyzer? I expect what it would show readings similar to a dipole with resonance at the operating frequency and an impedance (resistive) of somewhere in the order of 60 ohms. plus or minus -- is this a correct assumption?

OR -- does anyone on the group have any suggestions that will tell me when the system is properly adjusted -- the simpler the better!

Once I have found how to do this, I can put tape markings on the roll of counterpoise wire to show the appropriate length for each band or narrow band of frequencies in which I will be operating.

I have already tested the hole -- it is just a little less than 1/4 inch diamater, but that seems to be enough to let both sidebands through -- I carefully tested that using AM which proves that two sidebands can fit through the hole at the same time, which allows me to further assume that either the upper or lower sidebands should squeeze through easily!   :-)

Thanks in advance for any assistance you can provide in this matter.

Irv VE6BP

On the air finally but afraid to get to close to the mike! I may have
to use rubber gloves and teflon lip gloss!

Since you started this whimsical line of reasoning, you dare not object: Buy a plastic microphone. Har-har-HAR-dee-har-har! [Thanks to Ralph Kramden]

But seriously folks ...

You do have a coaxial cable from the radio to the tuner. Choke the bejabbers out of it. Either wind the coax itself into one or more physical coil(s) of the right proportions or use the W2DU method.

This will be useful for the former approach:
http://www.karinya.net/g3txq/temp/choke_impedances.png
It illustrates that no single coil really does it.

... and this for the latter:
http://www.qsl.net/ta1dx/amator/W2du.jpg
Although your application doesn't involve using beads as a balun, per the illustration, the broad approach is the same: blocking common mode currents.

"Sal"
who chokes his cables and gets no shocks

Irv,

I think you will find it difficult to tune up using a MFJ-949E, random wire=
 antenna and a roll of wire run around your apartment. You will probably e=
nd up with a "hot mike" most of the time. Even if you get it all tuned up =
on one frequency as soon as you QSY to a different frequency you will have =
to change the counterpoise wire length. Finding the right lengths for diff=
erent frequencies and coiling/uncoiling the wire each time you QSY will get=
 old fast.

I have a better solution for you. Buy an MFJ artificial ground so that you=
 can use a fixed length of wire under the carpet and tune the counterpoise =
from the operating position. MFJ makes a standalone product called the MFJ-=
931 or a tuner that includes the artificial ground - MFJ-934. Here are som=
e links to these products:

http://www.mfjenterprises.com/Product.php?productid=3DMFJ-931
http://www.mfjenterprises.com/Product.php?productid=3DMFJ-934

Hope things work out for you and that you get back on the air in the near f=
uture. Let us know how things work out for you.

Roger

I once had the little B&W vertical in a 3rd story apartment window. To
tune it, I used an SWR meter and simply unrolled my single
counterpoise wire across the rug until the swr was 1:1 for the band in
use. The counterpoise was on a wire spool. I never actually measured
the counterpoise length -- I simply found 40 meters meant the wire
went from the bedroom window to the kitchen.

Thanks Sal, Roger, and Bob as well as
the many others who have not yet replied
-- actually my mic is plastic.

I truly appreciate your assistance, but I think
I really need to explain my rationale somewhat.

The real intent of my questioning is to provide
a counterpoise system whereas the tuner does
not just have an unbalance by simply feeding
the random wire, but a balance achieved
whereby the counterpoise connected to the
tuner acts as the other (missing) half of the
unbalanced system, thereby balancing it just
as the ground image does with a quarter wave
antenna. Does this make sense? If not, wait till
you read further about MFJ and the push and
pull explanation.

I have two tuners at my disposal -- one is an
MFJ-949E Deluxe Versa Tuner II -- a common T
match configuration. The other is an MFJ-1625
Window/Balcony Mount Antenna which contains
matching circuitry and also a loading coil
for tuning the counterpoise wire or wires.
I hope to use the 949E, if I can resolve the
matter of knowing when the counterpoise
is properly adjusted. It is this matter that
I am trying to resolve to my satisfaction. I
could equally use the MFJ-1625 which is
just an MFJ-1623 with a 12 ft whip and
an 80m loading coil.

I'm fairly well read on antennas, but still my
knowledge of this monumental subject is very
limited i.e. to me a Smith Chart is something
belonging to a hospital patient named Smith.
I sort of understand the concept of the
counterpoise acting as the missing half of the
system, but have difficulty putting it into words.

MFJ, in the MFJ-1625 Manual say....

QUOTE
It is always important to have a good RF ground,
provided by the counterpoise, when using any
whip or long-wire antenna. This is because the
MFJ-1623 tuner needs something to "push"
against in order to force current into the antenna.
If a good RF ground is not available, RF will usually

find its way back into the power line (RFI), transmitter audio circuits (RF feedback), or the operator (RF burns). Water pipes provide good dc and ac safety grounds, but they are often inadequate for RF grounding because they are long single conductors. RF grounds require large "spread out" surfaces with direct multiple connections to the equipment ground point. Water pipes, heating ducts, or multiple ground rods may work (especially if they are all connected together with jumper wires), but the best RF grounds are radial systems or multi-wire counterpoises.
UNQUOTE

I have to admit that this explanation contains terms like long-wire antenna used in what I think might be confusing or ill-defined ways, but the idea of push and pull of antenna current feels right. If this is not already confusing, it is the MFJ-1625 Manual, but the tuner is an MFJ-1623. Many hams use the term MFJ as standing for 'Mighty Fine Junk', and at times I agree, but I do have good skills as a technicial and find that a little resoldering and tightening of ground nuts turns it into somewhat better than any of the homebrew or modifications I have ever put on the air. I no longer have a house, shack, workshop, and tower, etc,etc,etc and am now working with largely storebought items and limited space.

I have considered a cabin in the mountains where I would not interfere with anyone around, but where would I find one with built in housekeeping and meals? Just the expense of the extension cord alone makes me shudder.

I am not as concerned about a case of 'rf lip' as I am about stray RF causing possible problems with the neighbours on all sides of me, with all my electronic toys such as computers, DVD players, the local fire-alarm system and other such things. The last thing I want to do is draw attention to the fact that I am running a ham radio station from my suite until I know I am not causing any problems.

Thusly, my goal is to provide myself with a first rate RF ground system, entirely contained within my suite, in order that I do not wake up at night with the fire alarms set off and great numbers of disturbed residents gathered around pointing at me and saying 'Ham! Ham! For Shame! For Shame!' and the Residents Council having special meetings to decide how to deal with me. They already think I'm crazy -- and I may be somewhat, but I don't want to make matters worse!

So, having herein explained my rational, lets see what help I can get in the way of producing the ideal indoor low-cost non-radiating counterpoise radial system.

Actually, I have lots of wire for the radials, the tuner contains a loading coil to assist in tuning the counterpoise, and my big concern is how do I determine when the counterpoise is operating effectively. The metering system in the tuner should reach a peak and subside on either side of the correct counterpoise tuning point, and what I really need to know is how to determine when the stray RF is minimized if not eliminated.

I have to explain that I do all this in a somewhat humorous manner, I find all my predicaments funny, but then I brought myself into them and this is the only way, short of outright denial, of dealing with them.

You have probably already noticed that I am a man of few words!

Irv VE6BP

P.S. In a previous topic where the matter of electrons escaping from the end of the antenna was hotly debated, I have solved that problem by forming a wee loop at the end of the antenna, thereby taking any of those loose electrons and feeding them back into the wire! I used the loop and a nylon cable tie to fasten the end of theantenna into the tree which supports most of it, thereby eliminating the cost of a ceramic insulator and it's accompanying end effect. I'm sure Tesla and Marconi could have used some of my simple practical solutions like this one, and perhaps negated the necessity of long discussions re electrons escaping from antennas.

You shouldn't need to unroll the wire at all since you're using a tuner.
Just hook it up and tune away.

Yes and perhaps I have a workable idea to get there.

First, an assumption: Your long wire out the window frame has only a short run to the tuner. That is, the tuner is on the same wall as the window frame and is near the window. How'm I doing so far?

Along that same wall, stretch out a heavy piece of straight wire -- can be insulated but you'll cut through the insulation as needed -- from corner to corner. It's like a workbench ground bus but it's not grounded, per se.

Attach the tuner ground to it.

Buy two (maybe more) locking metal tape rules. Craftsman, Lever-lock.   At the zero ends, securely bolt or clamp the metal tape rules to the ends of the heavy wire in each corner. Yes, you're ruining the tape rules by mutilating the ends but we know you're desperate. Courage, man!

Stretch out the tape rules until their lengths become whatever you need for a workable counterpoise, recalling that HF antenna elements (and counterpoises) do not need to run in perfect straight lines. Zig-zagging is your friend in a confined space. Even go up the wall(s) in the far corners.

This method, if it works, has a bonus. Once the lengths are established for each band, the exact lengths can be eyeballed directly off the tape rules and noted. Alternatively, just scrawl band numbers on the walls. (Hi-hi)

"Sal"
Never one to let anything serve only a single purpose.

> multi-wire counterpoises.

So you should not unroll it but have "all connected together with jumper wires".

Jta is the same opinion: "You shouldn't need to unroll the wire at all since you're using a tuner.
Just hook it up and tune away."
The hook = jumped wire.

> >

> debated,

> I'm sure Tesla and Marconi could have used some of
> my simple practical solutions like this one, and perhaps
> negated the necessity of long discussions re electrons
> escaping from antennas.

There was also Sir Oliver Lodge. He demonstrated the escaping of electrons from the antinodes (see Fig. 2):

He also discovered that HF do not like the long conductors;
"The electrical charge stored in the Leyden jars could flow either through the very low dc resistance path provided by the loop of wire or it could flow across the very high resistance path through the air between the spark-gap terminals at B. It would seem that the obvious path for the charge to follow would be through the low resistance wire loop. Surprisingly, Lodge was able to produce very large sparks across the spark-gap, B, even though the dc resistance of the wire across the gap was only a fraction of an ohm.[4]"

I am trying to "descend you into the same bottomless pit"

S*

Bang on Sal -- the tuner is located about 18 inches from where the wire comes through the window, but on the floor along the wall with the window is the baseboard hot water heating unit so I can't really run anything on the floor along that wall. Similarly, although I understand your tape measure idea, there is a simpler solution which I tested last night and worked perfectly.

I arrived at a solution through the following note from Bob, K5QWG who wrote:

"I once had the little B&W vertical in a 3rd story apartment window. To tune it, I used an SWR meter and simply unrolled my single counterpoise wire across the rug until the swr was 1:1 for the band in use. The counterpoise was on a wire spool. I never actually measured the counterpoise length -- I simply found 40 meters meant the wire went from the bedroom window to the kitchen."

I thought it made perfect sense and even downloaded the instruction manual for the B&W AP-10 Windowsill Antenna which told me the same thing as Bob wrote -- and it worked perfectly.

I too used a spool of wire connected to the ground post on the MFJ-949E tuner, and unrolled it away from the tuner and antenna, across the floor and through the room. At that point I tuned up on frequency, adjusted the tuner for minimum SWR (nearly 1 to 1) and that was that! It worked beautifully.

Your idea with the tape measures would have worked as well, but would have been a little more expensive and possibly unworkable due to the heater. Instead, I simply put a tape marker on the counterpoise wire at the length where it worked well on the band tested (80M). Now, when I want to operate all I have to do is unroll the spool to the tape marker and Presto! I can go on the air! Of course I have noted the tuner settings, and will also add further tape markers on the counterpoise wire for the different bands, and note the tuner settings as well.

My next step may be to cut counterpoise wires for each band of operation and permanently lay them along the wall this negating the need to roll and unroll the spool of wire each time.

With time there may be some minor changes. For instance how far across the bands can I tune without any significant change in SWR. I might also try putting a loading coil in the counterpoise line at the tuner end so that I can fine tune the counterpoise length electrically. I will build up a little RF sniffer just to check for local stray rf but that should no longer be a problem.

I could use the MFJ-1625 tuner which has a built in switched coil to adjust the counterpoise, but it only has a current meter, not an swr bridge. The MFJ-949E tuner has swr metering. Therefore if the loading coil for the counterpoise works, I can use the 949E and sell (albeit at a small loss hopefully) the MFJ-1625 set complete to some ham who is able to operate using the intended setup for the 1625. It is an excellent system, but because of all the metal in my building which negates indoor operation, and the inability to put the whip out of the window due to physical limitations existing in my suite, I cannot use it. I had not considered the limittions in my situation prior to buying the 1625 but it was worth the try. I might even keep it (I may have to if I can't sell it) for portable use when I go fishing. It would be an excellent setup on a picnic table or from a tent. Again, time will tell,

In any event, A BIG THANK You to all who helped in this discussion -- I can now get on the air and as soon as I have things tested and tidied up I hope to meet you there.

Irv, VE6BP

Irv,

Nice to hear that you got something working and are back on the air. However I want to point out some incorrect assumptions you made earlier about RFI and stray RF from counterpoises.

The subject of radiating counterpoises in an apartment was discussed in this Usenet group a few years ago. Here is a link that provides some more info for you.

How much does a counterpoise radiate? -
http://www.radiobanter.com/showthread.php?t=117807

The counterpoise you have inside your apartment will definitely radiate into the building as will the length of antenna running from the tuner to the hole in the window. In another post you said you were running QRP at 5 watts. You may not have any # RFI problems with other electronics in your building at these low levels. If you crank up the power to 100 watts I don't think you will be so lucky...

-
True. A few years back with 100 watts and an attic loop, I fried the solid state heat/AC thermostat. I put a ferrite choke on the leads of the new one.

Thanks Roger -- I already knew that but didn't at all consider it during my recent explorations into the counterpoise system. How I managed to ignore it defys explanation -- I keep asking myself how that occurred. I think it may have been a cross between psychological suggestion and some form of denial in wanting a good and clean signal.

In particular I really enjoyed the tipoff to RadioBanter.com which I intend to explore more, and the discussions were informative. In particular, where there are links to other threads I found some of Reg Edwards material which has always been worthy of reading.

I went to bed satisfied that I could now get on the air and not set off any alarms etc, and although I don't recall them when I woke up, I'm sure I must have dreamed about good times on the air again! I've been in and out of the hospital for a couple years and have not been on the air since about mid 2009. I'm better now and looking forward to lots of radio activity!

As I mentioned in earlier posts, I have never been power hungry and have generally operated in the under 25 watt range -- now I'm going to be what I call 'ham flyfishing' i.e. QRP.

Now I can do some further experimentation such
as using individual counterpoise wires for each band,
and possibly even a variable inductor to fine tune the
counterpoise, and assorted things like that. I have
never been as interested in operating as in the
technical aspects -- especially the eternal search
for the utopian small antenna/DX magnet. My
DX interest extends only in so far as it is the
on the air tests that tell you how well your
antenna system is functioning given a
non-adjustable set of propagation conditions.

Now I have only to look forward to a good
sunspot cycle and perhaps just a little more
global warming to help me through those
cold Alberta winters!

What's your call? Where are you located?
I saw a .ca somewhere but that doesn't tell me
much.

Thanks again,

Irv VE6BP

Gonna ham away my 'golden years'!

Irv,

Your goals are certainly valid.

As far as preventing RF from going where you don't want it to... the main issue MJF is talking about here is "conducted" RF. The RF energy on the "ground" side of your antenna connector is going to flow outwards through every conductive path available to it, including the "counterpoise" side of your antenna arrangement, and anything connected directly or indirectly to your rig's chassis (e.g. to the power supply and then onto the third "ground" wire in the household mains). The amount of current flowing through each of these paths will depend on the RF impedance of the path, with more current flowing through paths of lower impedance.

So, what you want is (probably) to have one or more counterpoise wires whose RF impedance is as low as practical, at the frequency in question. These could be quarter-wave wires, or they could be shorter or longer wires with an "active ground" (which is essentially a simple "antenna tuner" on the ground side, with an adjustable reactance to cancel out some of the reactance of a non-quarterwave wire).

You can also help keep RF "where it belongs" by adding common-mode chokes to your rig power cables, thus increasing the RF impedance of this path and helping reduce the amount of current which is conducted back into the building ground.

Another approach which may help, is to consider using an end-fed half-wave antenna, with a specifically-wound matching coil system. These are (in principle at least) largely ground-independent... the low-impedance side of the matching coil provides good RF paths for both the "hot" and "ground" sides of the antenna connection, and when properly adjusted they don't dump much RF into the rig ground or counterpoise.

These techniques may not help much, if at all, with *radiated* RF getting into places you don't want it. Even if you have an antenna which is fully balanced, and completely isolated from the building ground (e.g. battery powered), the "near field" RF from the antenna can be coupled into the building wiring, and start causing interference and "undesired operation". Unfortunately, a lot of consumer and industrial electronic equipment these days is very vulnerable to this... poor shielding/filtering. Speaker cables, telephone and alarm wiring, etc. can all act as antennas.

Not much you can do about this except try to route your antenna and counterpoise wires as far away from other wiring as possible, keep your transmission power down, and try to transmit during times when people are asleep.

Irv,

If you found the radio banter discussion interesting you will really enjoy the forum on restrictive antennas at eham. Pages and pages of stuff written by hams living in condos, HOA and apartments. Here is the link....

http://www.eham.net/ehamforum/smf/index.php/board,2.0.html

Now that you are feeling better you can start having some fun back on the bands. You might find some of the digital modes like PSK31, WSPR etc. fun and they don't generate "recognizable RFI" like CW and SSB.

Roger

Leyden jars? You're back that far? That's over 250 years ago! They
had no idea of RF then!

You really need to look at things that aren't so old. The authors you
are reading have been proven WRONG when it comes to antennas and a good
bit of everything else related to electricity.

Thanks for your reply Dave,

I'm learning a lot in a hurry, finding out that grounds can be just as complex as antennas, and all about the interelationship between the two.

I do have chokes on the power cord of my 12v supply and also on the supply cord between the PS and the rig.

Your half wave suggestion is not immediately forthcoming due to the physical limitations I face here however it is on my list of possible future condierations.

As per a previous post I have recently come into a treasure trove of inductors and capacitors -- variables of every type and sixe. With all this at my disposalI plan to fiddle about with tunable counterpoises, artificial grounds, and combinations thereof.

At least I'm on the air again, but because I gave all my gear away I've had to jump from old tube rigs into a QRP world with a teensy Yaesu Ft-817 that it appears will take some time to learn to operate with all its menus, settings, and such. I have to get new glasses and perhaps a magnifier too.

The saving grace here is QRP with which I hope to get into as little trouble as possible.

I'm a pretty good tech, and have fixed up and modified lots of stuff but now I'm going to have to do a lot of learning in the wild world of wire antennas and grounds.

Thanks for your good suggestions, and for taking the time to reply.

Possibly not, my connection to the news server hiccuped badly for about a half hour and a response didn't get posted. It was to our wonderful source of knowledge Blaupunkt Szechuan.

I have no idea how it got posted to this thread, but I'd like to.

tom

Thanks Sal -- I don't know what was happening -- it had me wondering. Darned newfangled computers! :-)

I'm spending the morning learning how to operate this little Yaesu FT-817ND -- it's going to take a bit of patience with all the menus and settings. I have a TS-820 I fixed up and gave to a chum who upgraded to a top of the linke TS-1Million or something and he offered it back to me. It would be a lot simpler, but one slip of the carrier or mic gain and I'm sure I'd totally reveal my thus far cleverly concealed ham radio operation!

Thanks again for getting back to Tom on the Leyden jar matter! It really had me confused.

Irv VE6BP

Unfortunately he is in this thread.  Fortunately not much.

I like your interpretation of his name much better than mine.

tom

No parts were missing any time the antenna was in use. I was able to fix the storm damage myself. The parts were lost during subsequent storage while I was overseas. Anyhow, all's well that ends well.

Yes, I'm sure. Neither of your links even mention electrons. You may
want to elaborate a little on why those two link are relevant.

As I previously mentioned, there are many ways to detect electrons,
such as a phosphor screen (CRT), electrometer, or a Wilson cloud
chamber:
<http://kennethfinnegan.blogspot.com/2010/12/build-your-own-cloud-chamber.html>
(Hint: Don't drink the alcohol). None of these tests will respond to
RF from an antenna.

> Electron waves travel.

>No doubt, and please give an example of an electron wave.

"Waves in plasmas can be classified as electromagnetic or electrostatic according to whether or not there is an oscillating magnetic field. Applying Faraday's law of induction to plane waves, we find , implying that an electrostatic wave must be purely longitudinal. An electromagnetic wave, in contrast, must have a transverse component, but may also be partially longitudinal." " A plasma is a quasineutral, electrically conductive fluid. In the simplest case, it is composed of electrons and a single species of positive ions," From:
http://en.wikipedia.org/wiki/Electrostatic_Wave#Terminology_and_classification

>One more
time. It is impossible for electrons to travel at the speed of light.
But RF EM waves travel at the speed of light. Therefore, it is
impossible for RF waves to consist of electrons. Electrons act as a

bucket brigade for "buckets" of photons.

In the space is the rare plasma. There are the acoustic waves and the electron waves.

>> And what about the "displacement current?

>If Maxwell had known about photons, he would never have invented
displacement current.

Displacement current = small restricted motions of charges in dielectricts
in altrnate electric field.
It be always true..

>Assume we have an ideal transmission line terminated in an ideal
capacitor with two plates. It's easy to prove that the displacement
current flowing from one plate back up the transmission line, through
the source, back down the transmission line onto the other capacitor
plate has to be traveling much faster than the speed of light. Does
that give anyone pause to question the very existence of "displacement
current" in reality?

What is the source of the heat in microwave oven?

It makes it possess the wave-particle duality function. There is nothing in physics to prohibit electron waves traveling at sub-light speeds. But it is impossible for an electron wave to travel at the speed of light. Yet we know that RF waves travel at the speed of light. Therefore, RF waves cannot be made up of electrons. Here's two of many web pages about electron waves:

http://www.rodenburg.org/theory/y100.html

http://hyperphysics.phy-astr.gsu.edu/hbase/debrog.html

The Big Bang is the source of all energy in the universe.  :)
Microwave photons are the immediate cause of heating in a microwave
oven. If you don't believe that photons can cause heating, go stand in
front of an active radar dish.

Not me but Stokes:
"The Stokes drift is important for the mass transfer of all kind of
materials and organisms by oscillatory flows."

Here you are the "oscillatory water flow".
http://en.wikipedia.org/wiki/File:Deep_water_wave_after_three_periods.gif
The " "oscillatory flow of electrons" is in the Dirac electron sea.
Each wave are inherently non symmetric.

Microwave photons are the immediate cause of heating in a microwave oven.

Photons are the wave packets. It apply only to natural light and the damped radio waves.

Todays radio waves are continuous.

>If you don't believe that photons can cause heating, go stand in front of an active radar dish.

There are the "oscilltory flow of electrons".

According to Wikipedia, Stokes Drift applies to wave motion in fluid dynamics. The article predominantly mentions water. Article makes no mention of its application to radio signals.

No.  The same effect occurs when you put the dish in vacuum.

"the wave-particle duality" is used only in textbooks.

>There is
nothing in physics to prohibit electron waves traveling at sub-light
speeds.

Electron waves travel in the Dirac electron sea with the speed of light.
Like the sound waves in the air.

In space are ions and electrons (rare plasma).
Electron waves travel from the Sun about 8 minute and the acoustic (ion
waves) a few days.

In vacuum is rare plasma (ions and electrons). Plasma is a conductor.
The electrons are free to move.

If the propagation of electromagnetic waves would be dependent on
residual electrons present in the imperfect vacuum (like in space),
there would be a tendency for propagation to become worse when the vacuum
would be more and more perfect.   There is no such effect ever observed.

This has nothing what so ever to do with electromagnetics.

You are a babbling idiot.

That's because there isn't any.

It only applys to fluid dynamics, as in water and gases, not free space.

Once again the babbling little idiot does a web search for a phrase or
word like "wave" and is too blindinly stupid to understand that the word
can have more than one meaning.

I am a little surprised that he hasn't posted something about WAVE actions
in WWII.

Since each individual electron's mass would be infinite, I guess
that's where black holes come from.

Sorry about your theory but radar signals travel at the speed of
light, a feat that is impossible for electrons.

No, I don't think so.  A microwave works by agitating the water molecules
because they are dipoles that twist around in the electromagnetic field.
As an increased level of agitation is equivalent to higher temperature,
this immediately heats the water independent of resistive losses.
(which of cause will be a factor when attempting to heat stuff that has
no bipolar molecules and/or when using a resistive container to bake
rather than merely heat something)

Try to resist the urge to "check back". The group will become accustomed
to your absence, eventually, and carry on as it should. You're
visitation might lead to another undesirable experience for you and then
the group might have another painful withdrawal when you leave again.
Try to be considerate.

Too bad your news client doesn't have a useful filter.

Recent, as in since 1900, has proven this to be inaccurate.

You will ignore, or discount with babble, this statement as you do with
all that have anything to do with current knowledge.

Mikek - THANKS for the link to Rescue Tape! That looks to be exactly what I need to protect the fiberglass base insulator, which is actually still in pretty good shape. I replaced the short section of braid between the matching box and the radial spokes with a nice bit of tinned braid strap. Everything came apart pretty easy and was cleaned with a green ScotchBrite pad, and this time I used plenty of Penetrox at the joints and on the threads. Excellent so far.

The antenna is mounted atop a ten-foot + length of hurricane fence rail which is mounted to a cheap three-foot RS galvanized tripod. The tripod is bolted to a T-shaped base fabricated from 1 X 8 pine such that the whole thing can be tilted down by removal of a stainless wing nut that holds down the rear tripod leg. The base is fixed to the ground with three really big tent stakes; a set of three dacron guys completes the simple installation.

Once again, many thanks to y'all for the good ideas!

If you were happy with it's performance when it was new - you should have bought a new one when the storm damaged it - before MFJ got their grubby paws on the company and cheapened it up.

It you was good at fabrication - you probably could have made the replacement parts yourself.
And how did it work great for your mom if there was parts missing.

This whole post is a misnomer.

Throw it away, buy a new one, put it up according to the manufacturers
specifications and hope that it works as well as the one you bought
years ago.

My theory is sentimental value is always 100 cents on the dollar.
Real world tells me that unless you put up the same exact antenna on the
same exact location and had the same exact propagation - nothing ever
works the same 100% of the time...

Who "has proven this to be inaccurate."?

Before Cate were Ampere, Faraday, L. Lorenz, Tesla and Dirac.

Your statement should be supported with names of scientists.

Things are changing.
From beggining to IWW the light and radio waves were the "electric waves".
After IWW they becomes the "EM waves".
In XXI century they are "electron waves".
http://en.wikipedia.org/wiki/Waves_in_plasmas

Where the oscillating species are electrons.

Continuous waves are opposite to damped waves.
Continuous with the changde amplitudes are AM (amplitude modulation) or FM.

>Sorry about your theory but radar signals travel at the speed of
light, a feat that is impossible for electrons.

Wind is like the electron beam. They travel with the "wind'  speed.
The sound and electron waves  like the oscillating species (electrons or
molecules). They travel with the wave speed.

Up to now we see distant stars. The plasma is produced by stars. So we are not in perfect vacuum.
My be that such is behind the last star.

Most of you wrote that your antennas work below the voltage necessary to start the electron emission.

But in reality the emission take place at all voltages.

" Attempts to understand autoelectronic emission included plotting experimental current-voltage (i - V) data in different ways, to look for a straight-line relationship. Current increased with voltage more rapidly than linearly, but plots of type (log(i) vs. V) were not straight"

"A breakthrough came when Lauritsen[13] (and Oppenheimer independently[14]) found that plots of type (log(i) vs. 1/V) yielded good straight lines. This

result, published by Millikan and Lauritsen[13] in early 1928, was known to Fowler and Nordheim.
Oppenheimer had predicted[14] that the field-induced tunneling of electrons from atoms (the effect now called field ionization) would have this i(V) dependence, had found this dependence in the published experimental field emission results of Millikan and Eyring,[10] and proposed that CFE was due to field-induced tunneling of electrons from atomic-like orbitals in surface metal atoms. From: http://en.wikipedia.org/wiki/Field_electron_emission

Electrons escape from each charged body. Your antennas emit electrons and for this reason they need the sink of electrons (the earth/chassis/ counterpoise).

Best Regards,

S*

Of course not.
Not only is this effect too small to be measured at voltages common on a transmitter antenna, the voltage is also AC so these effects will

cancel out along the cycle of the AC wave. The net result will be zero. There can only be a net current when there is a (large) DC voltage on the charged body, which is not the case on a transmitter antenna.

Great theory. If antennas emitted electrons, and electrons have mass, we could then build a rotating antenna powered by the electron belching reaction mass. Put the antenna on a hub, and watch the electron emissions turn the antenna as they fly off the antenna at ummm... the speed of light. A few hundred watts of power should be more than enough to move the antenna around. Yeah, great physics you have there.

Hint: How fast do electrons travel in a wire?
No, it's not the speed of light. It's called electron drift velocity.
<http://en.wikipedia.org/wiki/Drift_velocity>
<http://www.jensign.com/JavaScience/www/cuwire/cuwire.html>
For the above example, it takes about 12 hours for an electron to travel 1 meter in a copper wire. Not exactly at RF speeds.

Keep trying. Eventually, you'll get something correct.

That's funny.
I would improve for clarity by putting spaces between

Write in one cell:  =(-   A1^2  + 8)  .......... (result xxx(censored)
Write in another cell:  =(8  -  A1^2).............(result x(censored))

The result is same a yours, despite the spaces.
You may also enter negative numbers in A1 and also
decimal numbers, everytime a surprise.

Another Microsoft blunder?

w.

The "oscillating species" can be electrons (e.g. free electrons in a
wire) in which case the wave energy is carried by photons. The
"plasma" of an outer space vacuum is NOT made up of electrons but of
dark matter exotic particles through which photons can travel. Give up
on the silly electron theory, replace it with a dark matter theory,
and there may be more than a grain of truth in what you say.

Indeed it has been quiet.

It makes one wonder if the group requires the likes of Art, Chip, and Sz to provide enthusiasm for kicking off discussions :)

The air molecules travel with the speed of the wind. But they oscillate if
there is the sound source.
The speed of sound and the speed the wind are the different things.

The same is with the electron waves speed and the electron beam speed.
>
> Are you cleverer than Einstein??

Einstein is not one of the radio fathers.

wire) in which case the wave energy is carried by photons. The
"plasma" of an outer space vacuum is NOT made up of electrons but of
dark matter exotic particles through which photons can travel. Give up
on the silly electron theory, replace it with a dark matter theory,
and there may be more than a grain of truth in what you say.

It is not my theory.

Where can I find the "a dark matter theory"?

The air molecules travel with the speed of the wind. But they oscillate if
there is the sound source.
The speed of sound and the speed the wind are the different things.

The same is with the electron waves speed and the electron beam (drift)
speed.

Yes.
 When they escape at low voltages we call it "discharging".
Charge your antenna and measure the dicharging time.

No. "Once liberated, electrons are strongly repelled by the high electric
field near the electrode during negative voltage peaks from the oscillating
HV output "

> There can only be a net current when there is a (large) DC voltage on
> the charged body, which is not the case on a transmitter antenna.

In a transmitter antenna is the "oscillatory flow of electrons" with the net
current from the earth into air.

No. Excel's parser can't always tell whether you want to negate A1
before squaring or not. Don't be lazy; group with parentheses when in doubt.

-(A1^2) + 8
works exactly the same as
8 - (A1^2)

I see you didn't bother to include the part about it being dependant on
the work function, which means there is a minimum energy required.

Or more likely you just don't understand this anymore than you understand
anything else.

> Electrons escape from each charged body. Your antennas emit electrons and

I just installed one of these and did a lot of experimentation with the
tuning rings. This is a truly great low cost antenna for the higher
bands. I use it on 10, 12, and 15 meters. My worst swr is 1.45 to 1 on
```

15 meters.

The bad news is that the owners manuals tells you to cut a foot off the top whip to tune this for 28.4 mhz. This would be a very bad move. I tried this by installing a whip that was already a foot shorter. It could be tuned for 28.4 but not for the other bands.

This antenna can be tuned for a 1.0 to 1 match on 28.4 with just the rings. I settled on a compromise that gave me a 1.2 to 1 match on 28.4, a 1.3 to 1 match on 24.950 and 1.45 to 1 match on 21.35 mhz.

Do not install the ground plane kit. This narrows the bandwidth to be unusable for hams.

The price for this antenna rated at 2000 watts is about 110 bucks shipped. Hard to beat this performer. I only use 600 watts on these high bands. I use 1500 on the lower bands where you really need it.

And no I have no relationship with solarcon other than being a happy buyer. If anyone is interested, my rings wound up beings set at 4 turns down from the top most position possible.

Michael

The blunder is not understanding operator precedence in Excel.
http://office.microsoft.com/en-us/excel-help/calculation-operators-and-precedence-HP010078886.aspx

Unary operators are before exponentiation.

Using more parentheses generally helps.

-A1^2 is interpreted as (-A1)^2 not -(A1^2)

Please let me know how far you can communicate using air molecules.
There is a momentum transfer when moving air, but it dissipates rather
quickly. Comparing electron dynamics with pneumatics just doesn't
work.[1]

>The same is with the electron waves speed and the electron beam (drift)
>speed.

Same as what? There is no such thing as an electron wave. There are
electron beams, and radio waves, with very little overlap.

If think that electrons fly off the ends of an antenna, there should
be a way to directly detect those electrons. For example, a CRT has a
phosphor screen that lights up when hit by electrons from the electron
gun. If your mythical electrons are really there, you should also be
able to place a phosphor screen near a transmitting antenna, and have
it light up.

Also, if your electrons are leaving the antenna, and flying off into
the ether, there should be a rather large positive charge left on the
antenna. If you then claim that the transmitter is replacing the
electrons as fast as they are radiated, then the positive charge
should reside in the transmitter. If you then claim that the local
electric utility is supplying electrons to the transmitter, then the
utility generating station must have a huge positive charge.

> Keep trying. Eventually, you'll get something correct.
>S*

You're not trying hard enough. Open book, insert face, absorb
everything, and verify what you've learned using real world examples
and numerical calculations. If your theory of the moment can't be

reduced to real (i.e. non-quantum) physics, with real calculations, and real experimental verification, it's probably wrong.

[1] Maybe this will help. It's not a perfect analogy, but it's close enough. Find a billiard table and line up about 10 balls in a line and as close together as possible. Use another ball to hit one end of the line, and time how long it takes between the first impact, and when the ball at the end starts to move. Now, cover the same distance with just the cue ball, and without the line of billiard balls. Note how it take MUCH longer for just the cue ball to travel the same distance. The line of billiard balls represents the atoms in a conductor. You'll get electron transport at almost the speed of light in such a situation. The cue ball alone represents the electron drift in the same conductor. If the cue ball could be made to travel at the same speed as it did through the line of billard balls, the felt on the billiard table would probably show a deep burn mark.

For some irrational reason, that probably defies logical justification, I've decided to setup my PCR1000 receiver as an internet accessible receiver. There are about 7 programs available to do this, so I don't expect software to be a problem. The receiver will eventually be moved to a mountain top repeater site, which unfortunately does not have much room for an antenna. The receiver will tune from 0.1 to 1300Mhz. I don't wanna deal with an antenna tuners or switches.

Is there an antenna or combination of antennas that are suitable for such a wide tuning range and that is small enough to fit in a limited rooftop area?

I was thinking of a monstrous vertical biconical dipole for HF, a diplexer, and a discone for VHF/UHF/etc. For Field Day, I once made a biconical out of two trash can lids, with holes for the wires around the perimeter. It worked amazingly well but I never bothered to make measurements.
<http://en.wikipedia.org/wiki/Biconical_antenna>

Can anyone suggest something better, smaller, less ugly, or more practical?

One thing not to forget is there are relatively inexpensive
duplexers/triplexers/etc. from the likes of Comet and others.  Or roll
your own.

I know that doesn't help much on the low end of things but means a
couple discones on the mid and upper will do well.

And yes there will be some small to medium gaps because of the device.

If it's always receiving and you can make an amplifier with high input impedance throughout the frequency range, then you could use a short dipole 'doublet' - drawing insignificant current from the antenna would make its very low radiation resistance less of a concern. Its directivity gain would be almost constant because its radiation pattern comes from its (fixed) axial symmetry, but a wavelength^2 factor would apply to its effective aperture area. It probably wouldn't be easy to design a single high-input-Z amplifier over that frequency range, but there might be scope for dividing the range and combining the _outputs_ of several amplifiers, each fed by their own doublet.

Would you need any kind of 'monstrous' antenna if the requirement was always receiving? I could see that you might want something large to get the radiation resistance up if you were transmitting from it, but for receiving a high-Z amplifier becomes easier at lower frequencies. I vaguely recall that some of the companies that have offered professional 'radiomonitoring' (i.e. evesdropping) equipment, such as R&S, have used combinations of different types of element for different parts of the wide frequency band, but never anything monstrous.

Chris

I like to make my own diplexer/triplexer boxes.  In this case, only a
diplexer is needed.  The Radio Shack discone antenna will (allegedly)
work from 30-1300MHz.
<http://www.radioshack.com/graphics/uc/rsk/Support/ProductManuals/
2000043_PM_EN.pdf>
Below 30MHz is the real problem.  Also, none of the commercial
diplexers I could find had a 30MHz cutoff frequency.  Looks like I get
to build something.

>I know that doesn't help much on the low end of things but means a
>couple discones on the mid and upper will do well.

I've compared the performance of discones and biconical antennas.
Biconicals are better because the radiation pattern is towards the
horizon, instead of towards the sky.  It also has about 1-2dB more
gain.  However, I'm not in the mood for building yet another
mechanical marvel, and will probably use the discone.

>And yes there will be some small to medium gaps because of the device.

I can probably ignore the TV bands (54 to 700MHz) but I want most
everything else.

Thanks much.

<christofire@talktalk.net> wrote:

>If it's always receiving and you can make an amplifier with high input
>impedance throughout the frequency range,

Good idea. I've done that before with a long wire (about 200ft) feeding a 3:1 turns ratio torrid xformer. It was a bit lossy at low frequencies, but that doesn't matter because the atmospheric noise level is so high, that everything is buried under the noise anyway.

>then you could use a short dipole
>'doublet' - drawing insignificant current from the antenna would make its
>very low radiation resistance less of a concern.

A doublet may not work at a commercial mountain top site. Doublets require twinlead or ladder line down to the radio. The feed line will need to either go through about 3 meters of pipe, or through a coax bulkhead feedthrough. I could probably install the balun before it enters the pipe or building, but that might not be practical.

>Its directivity gain would
>be almost constant because its radiation pattern comes from its (fixed)
>axial symmetry, but a wavelength^2 factor would apply to its effective
>aperture area.

I don't have much in the way of expectations in the way of antenna gain. If it receives anything, I'm happy.

>It probably wouldn't be easy to design a single high-input-Z

>amplifier over that frequency range, but there might be scope for dividing
>the range and combining the _outputs_ of several amplifiers, each fed by
>their own doublet.

Do I really need an amplifier just to do an impedance downconversion? I would think a 3:1 xformer would be adequate.

Actually, it's quite easy to build a high input impedance RF amplifier. I've done it many times. A source follower will do the trick. So will a grounded gate amplifier. Better yet, a dual gate MOSFET amplifier or some kind of cascode amplifier derangement. All of them can be configured for a high input impedance and 50 ohms output.

However, performance may not be so wonderful. It's a tradeoff between gain, noise figure, and bandwidth. There's no easy way to make an amplifier that is ideal for all three. Pick any two. Actually, it's worse because blocking, overload, and dynamic range are also a factor. Putting a broadband amplifier on a mountain top full of broadcast stations and commercial radios is not a great idea. I'll probably end up with a transformer followed by an attenuator.

>Would you need any kind of 'monstrous' antenna if the requirement was always
>receiving?

Well, no... but bigger does tend to be better. I could probably use a base loaded whip, tolerate the mismatch losses, and live with the general loss of gain at the low end of HF. The site has an 80ft tower, where I think (not sure) I can install two outriggers, egg insulators, and build some kind of vertical wire antenna. Various configurations are possible, but the monstrosity I was considering is an HF biconical.
<http://www.google.com/patents?id=LJ9pAAAAEBAJ>
What I like about it is that it's 75 ohms over at least one octave of bandwidth. However, as each element approaches 1/2 wave at some frequencies, the impedance goes sky high. The trick is to put those frequencies in areas where I don't care to listen.

I could also fit a "fan" type dipole antenna or a wire simulation of a "bow-tie" antenna. However, what I was hoping for was some manner of fairly short antenna (about 3-6 meters), with a fixed LC network that yields a fair approximation of 50 ohms. 2-30MHz, without tuning. I've been playing with such a matching network in 4NEC2, but getting nowhere. Surely, such a thing exists.

>I could see that you might want something large to get the
>radiation resistance up if you were transmitting from it, but for receiving
>a high-Z amplifier becomes easier at lower frequencies.

True, but for there reasons I previously mumbled, I don't think an RF amp on an RF polluted mountain top is a great idea. Besides, additional RF gain at the low end of the HF spectrum is useless because of the high atmospheric noise levels. All the gain does is lower the receiver dynamic range.

>I vaguely recall
>that some of the companies that have offered professional 'radiomonitoring'
>(i.e. evesdropping) equipment, such as R&S, have used combinations of
>different types of element for different parts of the wide frequency band,
>but never anything monstrous.

Yes, but I suspect they also used antenna tuners to deal with the
mismatch. I could do the same thing, but don't have an easy way to
control the antenna tuner, especially since the receiver doesn't have
the concept of "bands".

Thanks much.

I have one and have never bothered to check it because I've never
actually used it. It's one of my backup backup antennas.

Time to test it.

Thats a good rule of thumb. However, this is a receive only antenna, which does not need to be perfectly matched and can be fairly inefficient and low gain. Even so, I don't think the radiation efficiency is going to be that horrible. They're mostly due to conduction losses (at HF) and dielectric loss (at UHF). For the high currents required for transmitting, these losses are fairly large for a short broadband antenna. However, in a high impedance receive only antenna, the conductivity loses are a much smaller part of the antenna impedance than in the transmit antenna.

It's much the same in the discone. The antenna VSWR averages about 3:1 over about 6 octaves of frequency. With such a high VSWR, it's not a suitable transmit antenna. However, for receive, it works tolerably well.

Well, he thinks that this is what is happening and therefore he believes that any transmitter should always be grounded so that the earth can supply the missing electrons and prevent the transmitter from being charged more and more.

However, we all know this doesn't happen. He himself has no way to verify it because he does not have a transmitter (or he is not bright enough to realize that maybe he has one in his pocket).

So he keeps insisting that the transmitter must be grounded or problems would occur because of the electron emission. When everyone agrees that these problems do not occur, he does not realize that maybe the electron emission is not there at the voltages involved, and he was wrong after all.

All is O.K. Oscillating molecules produce the electron waves and in this way
lost its energy rather quickly.
```

But no smaller species than the electrons.
Tunnig fork transfer its energy to air molecules, air molecules to electrons
and no next step.

It could not be wrong because such Giants as Ampere, Faraday, Stokes,
Lorenz, Tesla and Dirac were "using real world examples and numerical
calculations."
>

>
> [1] Maybe this will help. It's not a perfect analogy, but it's close enough. Find a billiard table and line up about 10 balls in a line and as close together as possible. Use another ball to hit one end of the line, and time how long it takes between the first impact, and when the ball at the end starts to move. Now, cover the same distance with just the cue ball, and without the line of billiard balls. Note how it take MUCH longer for just the cue ball to travel the same distance. The line of billiard balls represents the atoms in a conductor. You'll get electron transport at almost the speed of light in such a situation. The cue ball alone represents the electron drift in the same conductor. If the cue ball could be made to travel at the same speed as it did through the line of billard balls, the felt on the billiard table would probably show a deep burn mark.

Ampere, Faraday, Stokes, Lorenz, Tesla and Dirac analyzed and explained everythig.

"Maybe this will help":
1825 - Ampere publishes his collected results on magnetism. His expression for the magnetic field produced by a small segment of current is different from that which follows naturally from the Biot-Savart law by an additive term which integrates to zero around closed circuit. It is unfortunate that electrodynamics and relativity decide in favor of Biot and Savart rather than for the much more sophisticated Ampere, whose memoir contains both mathematical analysis and experimentation, artfully blended together. In this memoir are given some special instances of the result we now call Stokes theorem or as we usually write it. Maxwell describes this work as ``one of the most brilliant achievements in science. The whole, theory and experiment, seems as if it had leaped, full-grown and full-armed, from the brain of the `Newton of electricity'. It is perfect in form and unassailable in accuracy; and it is summed up in a formula from which all the phenomena may be deduced, and which must always remain the cardinal formula of electrodynamics.'' From:
http://www.electricityforum.com/a-timeline-of-history-of-electricity.html

"a small segment of current" = electron.

"the Biot-Savart law" = hydraulic analogy.

Teaching and science are the two different things. In teaching is the hydraulic analogy in science are electrons.

"It is unfortunate that electrodynamics and relativity decide in favor of Biot and Savart rather than for the much more sophisticated Ampere".

Maybe in 1900, but not today.
This is because it was found that an antenna does not emit electrons.

Oscillating (vibrating) molecules is a measure of heat energy. With
that explanation, it would be necessary for antennas to be hot in
order to radiate. Try again please.

>But no smaller species than the electrons.

Other than positive electrons, there is only one type of electron.

>Tunnig fork transfer its energy to air molecules, air molecules to electrons

As I previously mention, pneumatic analogies do not work well for
describing RF radiation.

>>>The same is with the electron waves speed and the electron beam (drift)

Nice dodge. Answer my question... same as what? What is the same as
your electron wave?

>> There are

>
>Like wind and sound.

Which is like an electron beam? Wind or sound?
Which is like a radio wave? Wind or sound?
How are they like each other?

>

>Cathode rays were idenified in 1895.

My antennas do not emit cathode rays. If they did, my neighborhood would be bombarded with electrons, potentially destroying everything it its path.

Please produce a reproducible test, that will demonstrate that charged electrons are being emitted by an antenna. Your Nobel prize awaits you.

>> Also, if your electrons are leaving the antenna, and flying off into
>> the ether, there should be a rather large positive charge left on the
>> antenna.
>
>You call it "static".

Static electricity? The word "static" means not moving. With static electricity, surplus electrons (or lack of electrons) are accumulated on an object, giving it a negative (or positive) charge. The point is that they are not moving, just sitting there. Ever try to stop an RF signal? You can't. You can slow it down through various materials, but you can't stop it. RF and static are not the same. Try again.

> >If you then claim that the transmitter is replacing the

>
>For this reason the all electronic equipment have the
>earth/chassis/counterpoise as e remedy.

In case you haven't noticed, power lines are a balance pair. For 3 phase, they are also balanced at 120 degrees apart. The ground connection is strictly for safety and is not required for proper operation. It's there for safety, in the event you decide to prove your theory by discharging the mythical positive accumulated charge to ground through your body.

>It could not be wrong because such Giants as Ampere, Faraday, Stokes,
>Lorenz, Tesla and Dirac were "using real world examples and numerical
>calculations."

Pick one sample calculation that demonstrates that electrons are being emitted by transmitting antennas. There are plenty of tests that will detect electrons. Pick one.

>Ampere, Faraday, Stokes, Lorenz, Tesla and Dirac analyzed and explained
>everythig.

True, but you haven't explained anything.

>http://www.electricityforum.com/a-timeline-of-history-of-electricity.html

Thank you for the history refresher. Unfortunately, I didn't see anyone claiming that antennas emit electrons. Could you be a little more specific.

>"a small segment of current" = electron.

Segment? So, if I take a conductor, and cut out a segment, I can walk away with several amps of current contained in that segment? Amazing.

>"the Biot-Savart law" = hydraulic analogy.

<http://en.wikipedia.org/wiki/Biot-Savart law>
I fail to see any mention of hydraulics in the above article. Also, your analogy was pneumatic, not hydraulic.

>Teaching and science are the two different things. In teaching is the
>hydraulic analogy in science are electrons.

I'm sure the teachers in this group will be thrilled to know that what they're teaching is not science.

>"It is unfortunate that electrodynamics and relativity decide in favor of
>Biot and Savart rather than for the much more sophisticated Ampere".

If there's a conflict, simple explanations tend to prevail.
<http://en.wikipedia.org/wiki/Occam's_razor>
Sophistication is for science fiction.

>w.

Static electricity or radio static noise? Static electricity should not be a problem as the PCR1000 probably has a 100K resistor across the antenna connector. This is standard on most radios. If not, I can easily add one to bleed off any excess charge.

At VHF frequencies, any generated radio static should not be a problem. The building is high enough that it might end up inside a thunder cloud, where precipitation static might cause trouble. Besides, there's not enough dielectric material on the discone to build up much of a charge. If the humidity is low enough and the wind speed high enough to create arcing, I'll have much bigger problems than to deal with than a little static noise.

However, there may be another problem. We try to use grounded and low impedance antennas on mountaintop sites in order to reduce induced currents from nearby lightning hits. Both my proposed antennas are ungrounded and/or fairly high impedance. Oh-oh.

The wind of course.
Sound is like the electron waves.

Totally wrong. The power lines and receiver antennas must have ground
connection.
"The wire antennas used with crystal receivers are monopole antennas which
develop their output voltage with respect to ground. They require a return
circuit connected to ground (earth) so that the current from the antenna,
after passing through the receiver, can flow into the ground. The ground
wire is attached to a radiator, a water pipe, or a metal stake driven into
the ground.[4"

"The electronic-hydraulic analogy (derisively referred to as the drain-pipe
theory by Oliver Heaviside) is the most widely used analogy for "electron
fluid" in a metal conductor".

In EM is "electron fluid". In science "electron gas".

Do you think that monopole antennas are the only existing antennas?
It seems you do.

However, that is not true.  A dipole antenna does not need a ground
connection as the output voltage is not with respect to ground, but
between the two terminals.

Couldn't stay away! I knew when I departed that I'd be back eventually -- but I didn't realize how quickly. I should have known. My only interest now is in antennas. I just moved into a senior's residence where outside antennas or anything on the roof are out of the question -- at least that's what they think. I will be QRP using a Yaesu FT-817ND.

Over the years, before assorted medical problems lay me low, I helped a lot of hams who thought they'd have to forgo the hobby (due to antenna restrictions) get on the air. Now it's my turn to help myself!!!

I tried working using an indoor antenna but with all the metal in the frame of the building and around the windows it appears that this option is out of the question. Even a wire loop taped to the window couldn't get WWV when a chum of mine was getting it 20 over 9! I tried dropping a line outside the window to near the ground, but it receives little if anything -- probably due to the capacity between the antenna and the building. I did find that if I strung the wire out perpendicular to the building it worked beautifully.

I have now drilled a small hole (about 1/4 inch) through the window frame and plan to string some fairly invisible or very low profile wire out from the window and over a nearby tree with the end hanging down through the tree. Using this with an MFJ-1625 tuner I should be able to get out well. The tuner has a separate inductor which allows me to tune the counterpoise (which I can run along the wall in my suite), and combining this with low power and some RF Chokes on the power supply line I should be able to operate. It's difficult to quit after over 50 plus years of ham radio.

In any event, once I get on the air I can consider other antenna alternatives, but the immediate need is to get a signal out and myself back on the air.

This afternoon I'm going to a surplus warehouse searching for some suitable wire to string. I have a couple of questions re my setup that I've never had to deal with before, so that will be my next posting on this group.

As for my problem re trolling I guess I'll have to use blocking techniques which I didn't want to have to employ in fear of missing some good information. In any event, here I am again and I'm happy again!

Irv VE6BP
Calgary, AB

It also applies to solids, liquids, vapors, smog, and partial vacuums.
If it's warm, it has molecules that vibrate. Now, how does mentioning
hot air prove the existence of electron waves?

Really? If transmitting RF radiates electrons, what does your
belching hot air produce? Pneumatic particles? Where' the analogy?

>>>Cathode rays were idenified in 1895.
>>
>> My antennas do not emit cathode rays. If they did, my neighborhood

>The cathode rays travel to the anode.

I have a cathode ray oscilloscope next to my radio. For some odd
reason, my radio fails to detect the cathode ray emissions. Perhaps
that's because an electron beam is not oscillatory and therefore does
not radiate in the RF regions?

>> Please produce a reproducible test, that will demonstrate that charged
>> electrons are being emitted by an antenna. Your Nobel prize awaits
>> you.
>
>It was done before the first Nobel prize.

Well, if the Nobel Prize is insufficient, permit me to offer a
different prize, for which you seem qualified:
<http://en.wikipedia.org/wiki/Pigasus_Award>
Should you actually write a paper or produce an electron belching
transmitter, methinks this award would be more appropriate:
<http://en.wikipedia.org/wiki/Ig_Nobel_Prize>

<http://www.improb.com/ig/ig-pastwinners.html>
You may need some help with the form and structure. I recommend the
Journal of Irreproducible Results as a suitable guideline.
<http://www.jir.com>
For example:
<http://www.jir.com/turboencabulator.html>
Be sure to include me in the credit for inspiring your research:

>They travel into the earth.

Somehow, I've failed to notice electrons piling up on the ground.
Presumably, you're suggesting that they are falling from the sky due
to the effects of gravity. Well, that might explain my inability to
work DX with my ungrounded antenna, but does not explain how radio
functions in outer space, where there is no earth ground.

>>>For this reason the all electronic equipment have the
>>>earth/chassis/counterpoise as e remedy.

>Totally wrong. The power lines and receiver antennas must have ground
>connection.

Simply stating your conjecture, and quoting outdate and erroneous
conjecture does not make it correct. As I previously asked, can you
produce an experiment that would conclusively demonstrate that
electrons are being produced by RF transmissions, and that RF
propagation ceases when the antenna ground is removed? Please keep it
simple, like explaining how an ungrounded balanced dipole functions.

>"The wire antennas used with crystal receivers are monopole antennas which

>the ground.[4"

Congratulations. You've discovered the counterpoise. That's a good
idea (but not necessary) for a monopole, where the grounded
counterpoise forms the missing element of the dipole. However, that
doesn't demonstrate or prove anything about other antennas, most of
which have little use for an earth ground.

>In EM is "electron fluid". In science "electron gas".

The only electron fluid that is currently valid is in plasma physics, which has little to do with RF transmission. Could you kindly enlighten me as to how one derives RF emissions and propagation from plumbing? I couldn't find anything using Google.

>> I'm sure the teachers in this group will be thrilled to know that what
>> they're teaching is not science.
>
>Jimp is a teacher.

For a short time, I was a substitute teacher. I only taught one high skool science class for 2 days. However, I taught science, not technobabble.

Everyone lies, but that's ok, because nobody listens.

>Here no conflict. The hydraulic analogy is enough for kids.

It's not enough for me. Please explain how plumbing can be used to demonstrate RF transmission and propagation.

I can see that I'm making no progress at showing you the error of your ways. Methinks it's a hopeless task. I have a computah and a radio to repair on a fairly hot mountain top and will be too busy to debunk your rubbish. Please carry on without me.

Yup. As long as what you're giving up has a worthwhile advantage to
something else, go for it.

I can address that but, alas, not with encouragement.

When I was working, my domain included Navy shipboard antennas, including broadbanded HF transmit antennas, fed by banks of four or eight couplers through 50-ohm Heliax. (Yes, I know your application is receive-only. Please stick around.)

When a ship had the usual three antennas, they covered the range of 2-6, 4-12 and 10-30. At each one's feed point, a fixed, passive matching network using two, three or four reactive components brought the antenna inside the 3:1 circle on a Smith chart. (We didn't adjust them, we just periodically inspected and tested them. Why, Ye-es-s-s, we usually found loose, missing or corroded hardware on the mast. Why do you think we climbed up there?)

I mention this because the Navy tried to get better by doing HF transmit using only two broadbanded antennas (2-9 and 8-30) but had to relax the spec to a 4:1 SWR.   It worked on a few ships, but the radiomen often encountered freqs that were difficult or impossible to tune, so they'd revert to a whip antenna with a base coupler, like the Harris RF-601.

A good passive matching network for 2-30 seems unlikely. The Navy would have bought them by now if "surely such a thing exists."

1. Is there wire with camoflage insulation? (just kidding!)
I plan on using wire with beige or tan colored insulation. I
think sky blue or grey would provide the wrong contract.
Any ideas on this?

2. The far end of the antenna will be hanging from and in
the branches of a tree. I will only be running 5W (if I'm lucky)
and wonder about the voltage at the end of the wire. Will some
heat shrink provide suitable insulation to prevent corona from
starting the bush on fire? Is there a better idea? I will be
using PTFE (Teflon) insulated wire.

3. I'll be running the wire from inside my suite through
a 1/4 inch hole in the aluminum window frame. I was going
to feed it through a plastic straw to prevent chafing and
possible short circuiting. Any suggestions on the best way
through the hole to prevent any problems?

4. Is there a way to tell if the glass in my windows has some property that greatly attenuates signals? I'd ask the management but I don't want to trigger them into realization that future QRM will probably be emanating from my 'shack'! I plan to work the world while remaining invisible to those around me. If asked, I'll just explain that the wire is an antenna for my short wave receiver!!!!

This is the first time I've had to use a store bought rig! Until now I've either had modified surplus or burned out rigs which I rebuilt. I've always been an advocate of low power, but real QRP is new to me too -- and I equate it to the difference between dynamiting ponds and fly fishing! Time will tell! :-) When I became ill I gave away all my 50+ years accumulation of valuable ham radio equipment, tools, test equipment, and books -- collectively A.K.A. "Junk". It's fun starting from scratch -- at least my shack is not a terrible mess -- YET!

Do folks still mail QSL cards? Or can I settle for emailing a graphic equivalent of my own design? I've been off the air for a couple years now and think that things may have changed while I was out of the picture. This is not a big problem as printing and using the local buro shouldn't be too much of a problem. The hundreds of rare QSL's coming into my mailbox my invite unanticipated curiosity from the management.

Thanks in advance for any ideas you may have. This is the first time I've run through a metal window frame or dropped the wire into and among the branches of a tree.

Dunno.. From what I notice, lighter colors may blend with the sky at times, but they also reflect light more, which can cause the wire to stand out more at certain times of the day.

No problem with that.. 5 watts is not enough power to start anything on fire.. Even 100w will have trouble doing that in most cases. Only when I was running high power have I noticed arcing and burning of tree branches touching the ends of antennas. You can use almost anything as an insulator and should have no problems with QRP.

I suppose that would work ok.. or maybe run and melt some thin
heat shrink tubing at that point..

>

Glass is fairly RF invisible I think.. Should be no issue.

Low power can do fine if the antenna is decent.

>

I don't do QSL cards myself.. In fact, I've never sent anyone a
QSL card ever.. And I don't need any to send me one, but of course
still many do.. The CW contacts are much more likely to generate
QSL cards than the typical phone jabber..
The way I look at it, is I know I worked the people.. I don't
need paper proof of it.. :/
Maybe you could get a PO box, and assign it as your new mail
address, and have someone check the mail every once in a while.

I've considered that. The stretch from my window to where the
wire will enter the tree is such that there will be no one below, and
anyone walking in the area and looking up will be looking mainly
toward the building which is various shades of brown. The chance
of anyone seeing the wire against the sky is very small if at all. I'll try
that
light brown or beige first but it will be easy to change. The only
real time involved has been in planning what to do.

I sort of figured that, but your confirmation is indeed welcome. In
fact, Mark, I'm really pleased to see your reply because I've always
enjoyed your opinions and advice on antennas.

Until something better comes along, reinforcing the wire with some
heat shrink tubing, and running it through a heavy soda straw should
do the trick -- in fact now that I think of it, you can buy heavy straws

for kids and I'll pick one up tomorrow.

I'm still not sure on that either -- I've heard that leaded glass
can be a problem, but I'm not even sure what kind of glass is
in these windows. As it is, I'm not pushing RF through the
windows, but have considered a small magnetic loop located
inside, in which case I'd like to know.

I have a chum who was running an FT-101 here in town
through a G5RV 3 feet or so above his roof. He was one of
the top DXers in town. One day he suggested that things weren't
quite right so I went over to have a look. I told him to tune up
whilie I watched. He went through the correct tuneup procedure
as per the book, but never readjusted the Carrier Level adjustment
when he began operating. I had him repeat the procedure and
the same thing again! It turned out that the Manual doesn't really
tell you what to do beyone the tuning point so he left things as
is, and worked mucho countries running only 15 watts! It
goes to show what lower power can do, and also that what you
don't know won't hurt you!!! Once, in my shack, I set my rig
on 20m with about 5 watts of output. I made a call, and got
an immediate answer from a fellow who I had elmered back
in the early 70's!!!! We'd lost touch for all those years and had
been looking for each other. I was here in Calgary, he was down
in Silicon Valley!!

I seldom QSL'ed unless requested, but I do a lot of CW work
(almost as much as phone)  I'll play it by ear in the meantime.
One sad thing about QSLing -- when I got ill, my brother and
sister had a big sale and sold a lot of ham stuff (the rest I donated
to the local ham club). Some stuff that I would like to have kept
disappeared -- whether sold or not I don't know and never will,
but my collection of QSL cards going back to 1958 and over
four callsigns went somewhere -- my logbooks too!  Such is
life, but I'm just lucky to be able to start life over again and have
the fun of doing it!  This is really net -- back to basics and
climbing the ladder again!  At least I never had DXCC to lose!
>
Thanks again for your thought provoking and sage
reply.Much appreciated!

>1. Is there wire with camoflage insulation? (just kidding!)

No, but you can easily dye vinyl or PVC insulation in whatever colors you find useful. I once built a wire striping machine, that produced a red and white "candy cane" pattern. Please don't ask why.

>I plan on using wire with beige or tan colored insulation. I
>think sky blue or grey would provide the wrong contract.

I think you mean contrast, not contract.

There are vendors that sell "stealth" antenna wire. It has a copper plated steel core wire and clear insulation. Or, just the copperweld wire, and no insulation.
<http://www.universal-radio.com/CAtalog/cable/polystealth.html>
<http://fushicopperweld.com/en/bimetallics.html>

>Any suggestions on the best way
>through the hole to prevent any problems?

If you drill through the wall, drill at a slight angle so that water will drain out of the wall, rather than into the wall. Use PVC electrical conduit parts for the feedthrough.

>4. Is there a way to tell if the glass in my windows
>has some property that greatly attenuates signals?

Yes. Read the label on the window. If it says Low-E glass, it's probably coated with Titanium Nitride to reflect infrared. TiN is about 40 ohms per square, which is highly lossy at RF. You can test it with a cell phone. Compare the signal strength on both sides of

the window. If there's a drastic drop in level through the window, you have Low-E glass. Note that all new construction and remodels in California have required Low-E glass for the last 10 years or so.

Experience: I built a 10m sleeve dipole from copper pipe and I was justifiably concerned about voltage at the end where the feedline entered, so I encased the coaxial feedline in a length of PVC pipe. It acted as a separator.

This arrangement necessitated making one element larger than planned, so to accomodate the PVC, but it apparently worked. I never suffered an arc-through.

Today: If you were to secure the tree-end of your wire entirely within a length of PVC pipe, you would guarantee a separation of <enter PVC wall thickness here> millimeters from anything else. If you then glue some additional PVC fittings onto this "insulator," you can use them for mechanical attachment to <whatever> in the trees. Either that or hang the PVC from/within tree branches.

Good luck

I used to use a little FT-7 transceiver portable quite often,
and it was about a 20w input radio, and did about 10 watts out
on most bands.
Using any decent antenna, I never had any trouble working the
people I wanted to, and this was usually on 40 and 80 meters
using NVIS paths.
I remember one time I was camping out at Lake Amistad near Del Rio,TX.
I rigged up a dipole for 80m, and had it hanging between two short
trees. The antenna was only about 5 ft off the ground it's whole
length. Even with that low antenna, and the appx 10w output on SSB,
I was still in the S9+ range to most of the various people I was
talking to in say San Antonio, Dallas, etc..
For those type conditions, I would generally prefer 100w, but 10w
will usually get it done if need be. Only on the noisier nights
might it be a real issue where the extra power is needed.
These days my portable rig is the 100w Icom 706mk2g. And of course,
I can adjust the output power level to whatever I want.. I think the
minimum it will do is around 5 watts or so.. maybe slightly less..
But unless I'm worried about my battery, I let it rip at 100w..
The battery is rarely an issue as I usually can charge it off the
vehicle every once in a while.

Sal and Jeff, (and Mark)

Thanks for your thoughts and input on my intended system.

Jeff -- I did mean contrast -- my darned keyboard is getting old and confused, just like me!

I just want something quick and cheap so I've ruled out anything like copper clad steel and such. In my years of antenna experimentation, I would set up the system, test it, and even though it worked well, could not resist the temptation to 'fix' it by tearing it down and setting up a new and supposedly improved MKII version. I never got much more gain or efficiency, but still had fun.

Just to clear things up on the geometry, the wire will run out the window horizontally to the tree (about 25 ft) and then drop vertically (another 25 ft approx) through the tree to just above the
ground. Sort of an inverted letter "L". It is just a random wire, and the best I can do at the moment
given my current situation.

The hole through the window frame is too small (1/4 in.) for conduit but I plan to use a heavy plastic kids drinking straw, tilted down on the outside, and plugged with some silicon seal at each end where the wire enters and exits.

That reminds me of a friend who drilled horizontally through his foundation and drove an 8 foot ground rod through it. The first rainfall seemed to find it an ideal means of draining the back yard into his basement and he ended up with about 4 inches of water in his basement!

Jeff -- thanks for the tip on testing the glass. I can't see any markings on it, but the test is quick and simple and will soon let me know if I want to follow up with antennas inside the window. I may even try loading the window frame (aluminum, 5 ft x 5 ft (approx)) using a handy sheet metal screw for the connection.

Sal -- I've built a number of monoband sleeve dipoles by simply sliding back the braid on the coax. They were always great performers, but in this case I think they might be too obvious -- stealth is the primary concern here.

A reminder -- the ground system will be tuned counterpoise wires running along the wall inside my apartment. I have an MFJ-1623 tuner which will handle tuning the antenna and the counterpoise in a very nice compact arrangement with only one meter to watch!

Mark, NM5K has already calmed my concerns re corona and a reenactment of the burning bush bit, however I will cover the last few inches of the dangling portion with some heat shrink tubing, A small loop in the end will allow me to fasten the end with a plastic cable tie.

I'm really having fun with the planning stage -- with all this taken care of beforehand I will hopefully be up and on the air tomorrow. Only one factor can hold me back, and that is that the sale of my condo concludes tomorrow, and at the same time we have a very much contested Provincial election -- the equivalent of your state elections. In between I hope to gather the necessary materials and get operational.

Thanks again guys for your trouble and assistance.
It's all food for thought and I appreciate it. I'm really having fun and don't even have any wire out the window yet!

73

Will your 25ft span of copper wire support a few birds? If not,
please reconsider copperweld.

Do you have an antenna tuner? The FT-817ND does not have a built in
antenna tuner. You're going to need one with your random wire and
random configuration.

>The hole through the window frame is too small (1/4 in.)
>for conduit but I plan to use a heavy plastic kids drinking
>straw, tilted down on the outside, and plugged with some

Ummm... is this an existing hole are you going to drill a new hole?

The modern windows that I've seen have the glass extend almost to the edge of the frame with only a sheet rubber spacer in between. You're highly likely to drill through the glass if you decide to drill the frame.

>I may even try loading the window
>frame (aluminum, 5 ft x 5 ft (approx)) using a handy
>sheet metal screw for the connection.

With 5 watts, that might work. Forget about building a magnetically coupled loop. You would need to split the frame at some point, and install a variable capacitor. That's probably not going to happen.

If your window proves to be uncoated glass (unlikely), you might consider two squares of aluminum foil on both sides of the window to couple through the RF via a ladder line. You won't get much capacitance so it won't work on the lower frequencies, but should be tolerable for the higher bands.

>A reminder -- the ground system will be tuned counterpoise
>wires running along the wall inside my apartment. I have an
>MFJ-1623 tuner which will handle tuning the antenna and
>the counterpoise in a very nice compact arrangement with
>only one meter to watch!

Good, you have a tuner. However, that's designed specifically to handle a 12ft balcony mount HF antenna. I don't know what it will do with a longer antenna. Looking at the schematic:
<http://www.mfjenterprises.com/pdffiles/MFJ-1623.pdf>
it seems to be a crude L match, which isn't going to match every combination of reactance and frequency. The meter does NOT indicate VSWR, so you really won't know if the tuner is effective. My guess(tm) is you're going to purchasing a more elaborate antenna tuner, a VSWR meter, or using a 12ft piece of wire.

I once used a large sheet of WELDED chicken wire under the carpet for a "ground". It has to be welded to prevent the galvanizing from forming diodes. It sorta worked but nobody wanted the lumpy carpet.

Yes. The electron beam is a electron wind.

"The photoelectric effect will cause spacecraft exposed to sunlight to
develop a positive charge. This can be a major problem, as other parts of
the spacecraft in shadow develop a negative charge from nearby plasma, and
the imbalance can discharge through delicate electrical components. The
static charge created by the photoelectric effect is self-limiting, though,
because a more highly charged object gives up its electrons less
easily.[53]"

No. The counterpiose is the ground.

Heaviside derived RF emissions and propagation from the plumbing. RF are the
rotary oscillation.

The oscillatory vibrations are demonstrated as the cylinder quickly rotated
to and fro in a water or solids.

You finally agree, but for all the wrong reasons. :|
Reboot and try again. Like Will Robinson, you are still
lost in space.
I'm not even going to try to explain why, as you likely won't
believe a word I say.

In 1867 Lorenz wrote: " Ludvig Valentin Lorenz, "On the identity of the
vibrations of light with
electrical currents," Philosophical Magazine, Vol. 34, 1867, p. 287-301"

http://books.google.pl/books?id=caJdQfAKHtMC&hl=pl&pg=RA1-
PA287#v=onepage&q&f=false

On p. 301 he wrote:
"The present general opinion regards light as consisting of backward and
forward motions of particles of aether."
If this were the case the electrical current would be the progressive motion
of the aether in the direction of the electrical current."

In today's words: "Light is the oscillatory flow of electrons".

Light and radio waves are the same.

Are the radio waves the oscillatory flow of electrons?

I believe in each your word. But I simply do not know where in your
equipment the "large conductor" is.
Probably it is the coax: "Many conventional coaxial cables use braided
copper wire forming the shield".

I also belive in each Tesla's word. He discovered that in his secondary coil
is the oscillatory electron flow from the earth into the air.
Why is it impossible?
S*

The present general opinion regards the space as "rare plasma" (ions and
electrons).
So Are the radio waves the oscillatory flow of electrons?
 S*

In your statements, you never specify what a "large conductor" is.
Today, transmitters are often very small and still they work OK without
any earth connection.
How large should a "large conductor" be?

> Probably it is the coax: "Many conventional coaxial cables use braided
> copper wire forming the shield".

The transmitted signal flows only along the inside of the shield of the
coax. The outside is supposed to carry no signal. If it does, there is
a problem with the antenna system.

> S*

We do not operate our transmitters in the region where electrons start
flowing into the air, because we do not like arcing. Tesla did, but he
was in a different business.

Because RF EM waves are not made up of electrons. The particles that are flowing in an RF EM wave are photons. RF waves travel at the speed of light. Electrons cannot travel at the speed of light. If Tesla actually believed that an RF wave consists of electron flow, he was simply ignorant of quantum electrodynamics. That may be the reason why he failed to transfer large amounts of power through the air in an efficient manner.

Electron waves travel. Electrons have different speeds like the all gases.

He wrote that for this you must use the higher frequency than was possible
in his time.
Now all transfer large amounts of power through the air in an efficient
manner.
Light is an example. But now we have the free electron laser.

Here you are:
"". In electronic circuit theory, a "ground" is usually idealized as an
infinite source or sink for charge, which can absorb an unlimited amount of
current without changing its potential. Where a real ground connection has a
significant resistance, the approximation of zero potential is no longer
valid. Stray voltages or earth potential rise effects will occur, which may
create noise in signals or if large enough will produce an electric shock
hazard.
The use of the term ground (or earth) is so common in electrical and
electronics applications that circuits in portable electronic devices such
as cell phones and media players as well as circuits in vehicles such as
ships, aircraft, and spacecraft may be spoken of as having a "ground"
connection without any actual connection to the Earth. This is usually a
large conductor attached to one side of the power supply (such as the
"ground plane" on a printed circuit board) which serves as the common return
path for current from many different components in the circuit." From:
http://en.wikipedia.org/wiki/Ground_(electricity)

> Today, transmitters are often very small and still they work OK without

Electron do not start.
Electrons are flowing into the air (and vacuum) at each voltage.
The thin wire is the best "cold cathode".
What are your antennas made of?

Transmitters do not emit electrons. They emit electromagnetic waves.
You only see electric current in the feed to the antenna, not externally.
When the antenna is not driven relative to earth, this is not causing
current into the earth, and so no connection to earth is required.

But in my cellphone, the coax feeding the antenna is maybe only 1cm
long, or even shorter. How can you call it a "large conductor"?

What current do you measure in a wire connected to your 12v car
battery, and hanging freely into the air?
This is the current caused by your electrons flowing into the air.

"Negative corona take place at each voltage:
"A corona is a process by which a current, perhaps sustained, develops between two high-potential electrodes in a neutral fluid, usually air, by ionising that fluid so as to create a plasma around one electrode, and by using the ions generated in plasma-processes as the charge carriers to the other electrode.
Corona discharge usually involves two asymmetric electrodes, one highly curved (such as the tip of a needle, or a narrow wire) and one of low curvature (such as a plate, or the ground). The high curvature ensures a high potential gradient around one electrode, for the generation of a plasma.

Coronas may be positive, or negative. This is determined by the polarity of the voltage on the highly-curved electrode. If the curved electrode is positive with respect to the flat electrode we say we have a positive corona, if negative we say we have a negative corona. The physics of positive and negative coronas are strikingly different. This asymmetry is a result of the great difference in mass between electrons and positively charged ions, and so only the electron having the ability to undergo a significant degree of ionising inelastic collision at common temperatures and pressures.

An important reason for considering coronas is the production of ozone around conductors undergoing corona processes. A negative corona generates much more ozone than the corresponding positive corona. " From:
http://www.wordiq.com/definition/Corona_discharge

"the tip of a needle, or a narrow wire" is a source of the "cathode rays".
They were identyfied in 1895."

""the tip of a needle, or a narrow wire" is a source of the electrons.

For 12 V it should be the nanometers.

Take a rest.
S*

Which does not exist on all printed circuit boards.

You are again attempting to make something that sometimes exists into
something that allways exists.

There is no "large conductor" on many modern circuit boards so you are
wrong yet again.

Gibberish.

> What are your antennas made of?

Usually aluminum tubing or copper wire for fixed antennas and usually
chrome plated steel for portable antennas.

Antennas do not have a chassis.

Hello folks.

Anyone understand what Szczepan means by "oscillatory electron flow",
please? I'm assuming he means a sine wave or a push-pull current.

Regards, Ian.

Hello jimp.

Pity he can't define "large" or understand "ground".

No, it does not.

Corona only occurs with sufficiently high voltages.

The voltages on most antennas is no where high enough to cause corona.

> "A corona is a process by which a current, perhaps sustained, develops
> between two high-potential electrodes

There you have it: "two high-potential electrodes".

<snip>

>> But in my cellphone, the coax feeding the antenna is maybe only 1cm
>> long, or even shorter. How can you call it a "large conductor"?
>
> "Large enough."

There is no coax in my cellphone, my 2M handheld, or my aviation handheld.

The cases of all of them are plastic and there is no "large conductor" nor
is there any "ground plane".

Yet they all work.

You are a babbling idiot.

<snip>

> ""the tip of a needle, or a narrow wire" is a source of the electrons.
>
> For 12 V it should be the nanometers.

For 12V there is no corona as the voltage is too low to initiate a corona
no matter how small a tip you put on the wire.

> Take a rest.

Get therapy.

He was wrong on several counts.

He also died well before Einstein and others came along and got it right.

That's the problem with obsessing over stuff that was written 150 years
ago, a lot of it was found to be wrong.

Lorenz was wrong about the composition of light.

Marconi was wrong about antennas having to be grounded to work.

> In today's words: "Light is the oscillatory flow of electrons".

Nope, in todays words light is electromagnetic radiation that is visible
to the human eye.

> Light and radio waves are the same.

This is one of the very few true statements you have ever made.

> Are the radio waves the oscillatory flow of electrons?

No.

The phrase "oscillatory flow of electrons" is gibberish.

Hello Tom.

You're right - he is amusing. I suspect he has some old textbooks and is bouncing from one paragraph to another.

73 Ian.

I think that's a good thing. We wouldn't get signals from satellites otherwise.

Actually, that begs the question "which planet is the real ground"?

Reckon we could hang a dipole all the way from the earth to the moon?
What gain would it have and what frequency would it resonate on, I wonder.

73, Ian.

No.

> What gain would it have and what frequency would it resonate on, I wonder.

Well, lessee... gain would be the same as any dipole, i.e. about 1.76dBi
not considering resistive losses because you did not specify a conductor
size. Resonant frequency would be ~.372 Hz. This does not include the
"capacitive hats" of the earth and moon.

> 73, Ian.

Where would "ground" be?

Hello Ian.

I had wondered if that might be the case but I tended more towards
cut-and-paste by someone who find Wikipedia pages.

73, Ian.

Oh - sorry about missing that, John.
How about going for any two planets which form a straight line? This is surely better than relying on just one planet which might develop an eccentric orbit (which we could name the "S****pan orbit").
Besides which, someone, sometime in the future, might want to hang a long wire between the planets (but how much would the feeder cost).

Okay - if you prefer only on planet then I suggest Saturn (let's talk halo aerials) or Jupiter with its jolly red spot (well, you try getting a tube of cream THAT big).

I suppose the best evidence of using ground / planet is moonbounce - uses the ground / planet without an aerial at that end of the path.

73, Ian.

He is an idiot that cuts and pastes from web pages.

Most of the pages he uses are historical in nature.

I have no clue what motivates the little idiot to be such an idiot, but
I suspect brain chemical problems.

Okay. But how many planets have bounced from their "ground" a signal?
Does that mean that they are not really there, just an artifact of
telescopes?

Hello again. He reminds me of someone who is elderly and thinks that all textbooks are the same ... so reads the ones from the 1930s and 1940s. This fits in with the "Marconi was right" persuasion for, surely, Marconi was synonymous with radio (though those of us who know something about Marconi know that he developed radio from existing ideas).
I have had to help a few such people with "new" technology such as digital television, digital radio and digital cameras. They find it hard to accept that things have changed since they were young.
I'd like to know if Marconi saw his aerial as a device in its own right

(i.e. "here is a transmitter" and "here is an aerial") or simply as the part
of the transmitter that happened to be better at "projecting" a signal than
a piece of wire dangling from the end of a transmitter.

73, Ian.

Marconi certainly concidered an antenna to be a separate piece of equipment
and the word "antenna" comes from his use of the Italian word antenna, meaning
pole, to describe them.

It is becaue of his prominence the word spread to the general public.

> Electron waves travel.

No doubt, and please give an example of an electron wave. One more
time. It is impossible for electrons to travel at the speed of light.
But RF EM waves travel at the speed of light. Therefore, it is
impossible for RF waves to consist of electrons. Electrons act as a
bucket brigade for "buckets" of photons.

> And what about the "displacement current?

If Maxwell had known about photons, he would never have invented displacement current.

Assume we have an ideal transmission line terminated in an ideal capacitor with two plates. It's easy to prove that the displacement current flowing from one plate back up the transmission line, through the source, back down the transmission line onto the other capacitor plate has to be traveling much faster than the speed of light. Does that give anyone pause to question the very existence of "displacement current" in reality?

Back when physicists and engineers were ignorant of the existence of
photons, that was the best they could do to explain electromagnetic
fields surrounding free electrons being energized by AC signals.
Nowadays, we know that at RF, the electrons oscillate virtually in
place and it is the photons that are responsible for energy transfer
(flow).

Well, not exactly plonking, but unsubscribing from this group for
a while until the madness into which it appears to have descended
(i.e. where one troll can hook a series of responders who in turn
descend into the same bottomless pit!} I'll check back from time
to time to see if some degree of sanity has returned and may
then again subscribe to the one newgroup I really used to enjoy!

While I do not disagree with what you said, note the 's' in "Electron waves".

A particle may have some wave properties but that does not make it a wave.

Yup. In 1950, when I was 7, I acquired the Compton's Pictured Encyclopedia, 1930 edition. I was an avid reader and I loved those books.

However, it didn't take me long to start finding errors -- or perhaps "inconsistencies," to be kind -- with more recent thinking.

Nominally, those books were only 21 years old -- like from 1991 to today. But I presume many of the articles dated from prior editions, some maybe already decades old by 1930.

I use "plonk" as "Block the Sender." Not so with you?

The main problem is not in the articles, but in the strange way
you interpret them.  The article about ground explains what is
wrong with your reasoning, but you still don't get it.

Good evening Szczepan.

Your question "What the sparks are made of?" was answered in the posting
from jimp @ specsol.spam.sux.com dated 15 April 2012 17:06.

Are you having difficulty reading or understanding the emails send by others
and intended to enlighten and inform you and answer your search for
understanding?

Have you looked at any of the books I mentioned in an earlier posting,
please?

Kindest regards, Ian.

Use a static electricity dissipator:
<https://www.google.com/search?q=static+dissipator&tbm=isch>
Commonly found on airplane wing tips, fiberglass hull vessels, and

ungrounded towers prone to lightning hits. A 1M resistor to ground will discharge any static build up across a base insulated tower.
<http://www.lbagroup.com/international/tower-lightning-protection.php>
<http://www.lpsnet.com/ALS.asp>

I'm not sure why you're arguing about grounding antennas. There are plenty of examples of antennas that operate without a ground. If low frequencies are your immediate concern, may I point out that DF loop antennas are very popular on the beacon bands (200-400KHz). They also work nicely in airplanes, where there's no available earth ground. BCB is no different. There were plenty of antique home receivers that used either an internal or external loop (or loopstick) antenna, that didn't require a ground connection.

If BCB stations decided to use horizontal dipoles instead of vertical monopoles, a ground would not be needed. The only reason they need a ground is to act as the counterpoise for the monopole. This provides the missing 1/4 wave element of the dipole.

How kind of you.

>
> I am not going to fight over who invented radio, or the different types
> of modulation scheme's - since the days of spark gap transmitters.
>
> I tried to post some relevant information - but it seemed to get lost in
> the jumble.

The info you posted dealt with mostly mobile applications.
Only vaguely relevant to the statement at hand, which was a quote
from a long dead radio buoy, stating that no practical wireless
system exists, which is not connected to earth.

>

Most of the irrelevant blabber-gab deleted to save bandwidth,
except for this one..

 >There is nothing in outer space for the signals to bounce off of - so
 >they travel millions of miles in just a couple of seconds.

That I would like to see, being as it takes light from the sun
over eight minutes to travel from the sun, to the earth.. Try about
372,564 miles in two seconds.. Hardly millions..

>
> Or that some ham would be willing to spend 10's of thousands of dollars
> to buy a transceiver that does the same basic thing as a AM radio you
> can buy in any Walmart or Goodwill for a couple of bucks.

That's about one silly statement, unless the ham plans to do
nothing but listen to KTRH all day long. Most use them in other ways,
which most all of which the typical Wallace World special could only
```

dream of. I only wish Wallace World sold usable amateur radios for a couple of bucks.
I'd have several hundred more radios than I already have. :|

>

Does that mean they are all SOL?

>
> The OP wanted to debate the fact that some antenna's works best when we
> include some type of ground. Yes a good vertical transmitting antenna
> includes some type of ground to keep the signal from warming the clouds
> and being wasted.

Not all verticals require ground systems, and how did the clouds ever get involved?
Seems you may be confusing the benefits of feed line decoupling with the benefits of a radial system under a ground mounted monopole. :/

> A beam antenna does not have a physical ground, yet still works - maybe
> the ground reflections helps the signals to travel further.

Then maybe they don't.. Also, some directional arrays do use ground systems, if they are ground mounted.
But this statement does not mean Marconi's statement is correct.

> But we all know that effective communications requires the antenna to be
> as high as possible.

In some cases, it may make no difference how high the antennas are.
In others, it may mean a great deal.

> Only once you get to what is it 38,000 miles one antenna will transmit
> to one hemisphere - or is it what ever part of the earth you can see and
> will transmit no further.
> That is the point of diminishing returns.

Maybe so, but there are no structures that high for me to attach an antenna to. And I can't jump that high. :(

hi

I'll be traveling down to FL 4/16 wondering if there any hamfests that
might be around the area then?

Didn't see anyting posted but thought perhaps  a smaller local one could
have been missed by me

thanks

Consider what you find at n3fjp.com. I'm the local club's FD chairman and
we're going to use his network logging program this year. Our trials with
Field Day Logger 2.6 have all been satisfactory but I have no experience
with any other programs.

In the statement about AM Broadcasters you state about the ideal ground system & describe about the Radials but then ask why, That goes to show you don't know anything about Antennas, Transmitters. Feedlines, Matching, Efficiency, If you read farther you would have possibly learned something but you don't want to learn just bother the group. Nowhere in what you wrote does it state it is for static or what it is for except if you would read farther it would have told you...What about a balanced antenna, It has no earth connection & doesn't need one per your earth definition. If Maxwell was alive today & had read about all the improvements & discoveries that have been made & are still being made He would say He was wrong & that the answer to your question is NO.....I see you have started a new thread called Electron Gun but keep referring back to this thread for the answer. I'm very sure you know nothing about a electron gun, or a vacuum tube....To bad you don't know how to read or study & especially learn about anything...

In all answers no clear information if your "black box" have the
earth/chassis/counterpoise.
>
> Have you looked at any of the books I mentioned in an earlier posting,
> please?

I know what is in the books. I do not know if your ""black box" have the
earth/chassis/counterpoise."

Good morning Szczepan.

I think we have a language problem here. The answers to your questions ARE
in the books that I mentioned. If these books are not available in your
native language then I can understand your difficulties.

I recommended the amateur radio books because they cater for people who have
no prior knowledge of radio and aerials.I still haven't seen an answer from
you to my question "Are you discussing resonant or non-resonant aerials,
please?".

Kindest regards, Ian.

It seems to me that you do not know what the word "resonans" means.
We are discusing the earth/chassis/ counterpoise and the field electron
emission.

Best Regards,
S*

Hello Szczepan.
If you mean the Warsaw radio mast (
http://en.wikipedia.org/wiki/Warsaw_radio_mast) then you are incorrect. It
was not a dipole. Do you mean another tower which supported a dipole aerial?

I assure you that I do know the meaning of "resonant". I need to know and
understand it in order to match my radio to my aerials.

Kindest regards, Ian.

I am not arguing. I agree with you that " they need a  ground is to act as
```

the counterpoise for the monopole."
I hope that you agree with me that monopole on the plane/satellite has the counterpoise in form of chassis.

Is the field electron emission from the tip top of antenna or not?
I "do not know anything about Antennas, Transmitters. Feedlines, Matching,
Efficiency,"

You claimed that ANY transmitter with ANY antenna ALWAYS needs an earth connection.   That is incorrect. If Marconi claimed that, Marconi was wrong.

Now you are more and more restricting the playing field by talking about AM transmitters, monopoles, etc.   And by extending your definition of "an earth connection" to a chassis.

This of course leads to nothing. The original claim is still wrong.

Not.  There is no electron emission from an antenna when operated without
arcing, something that everyone except Tesla wants to avoid at all times.

That in Warsaw required the ground system:
""Large constructed half-wavelength dipole towers include the Warsaw radio
mast - the only half-wave dipole for longwave ever built."

S*

The original Marconi's claim was:

 In 1909 Marconi wrote:
 http://www.nobelprize.org/nobel_prizes/physics/laureates/1909/marconi-lecture.pdf
"The necessity or utility of the earth connection has been sometimes questioned,
but in my opinion no practical system of wireless telegraphy exists where the
instruments are not connected to earth.""By  "connected to earth" I do not
necessarily mean an ordinary metallicconnection as used for ordinary wire
telegraphs.The earth wire may have a condenser in series with it, or it may
beconnected to what is really equivalent, a capacity area placed close to
```

thesurfaceof the ground (Fig. 4).It is now perfectly well known that a condenser, if large enough, does notprevent the passage of high frequency oscillations, and therefore in thesecasesthe earth is for all practical purposes connected to the antennae."Is the original claim wrong?S*

Yes, the original claim is wrong.
It is wrong.
Wrong.

But you are not prepared to accept that.
Please stop arguing.

In the early days of radio, most experimenters tended to think of antennas as working by RF alternating currents charging (and discharging) a big capacitor in the sky via a long, vertical wire (or multiple wires, to increase the capacity, and to minimise losses).

To push and pull the current in and out of the capacitor, it was necessary to have a good, solid, zero-potential reference point, and the best one available was ground/earth (or, at sea, the hull of the ship). So, for the types of antennas being experimented with (and used) at the time, Marconi was absolutely correct.

Also, it wouldn't have taken them long to appreciate the benefits of bringing the antenna system to resonance on the frequency the operators wanted (rather than it simply being an act-of-God and hope-for-the-best affair).

But note that with Marconi's famous crossing the Atlantic experiment, I believe there is no documentation of exactly what frequency was used. Instead of it being something extremely low (which is what they expected), it is now thought that the signal which travelled 3000 miles would have been one of the many harmonic resonances of the antenna, as this would have been excited by the extremely wide band of frequencies created by the spark transmitter. Knowing now what frequencies cross the Atlantic in daylight, the signal might have been as high as 10 or 15MHz (frequencies which Marconi only dreamt about using!).

Very well. You are debating.

>I agree with you that " they need a ground is to act as

>the counterpoise for the monopole."

Not true. At higher frequencies, one can use the grounded coax cable feed to act as a crude counterpoise.

>I hope that you agree with me that monopole on the plane/satellite has the
>counterpoise in form of chassis.

No. You claim that because the monopole requires a ground, therefore all antennas require a ground. That's too general a claim and is not true, even for a monopole. For example, a very common antenna type at 2.4GHz is a "meandering 1/4 wave" antenna, which uses no ground:
<http://802.11junk.com/jeffl/antennas/laptops/slides/compaq-2120us.html>
Another example is the metal rim of the iPhone 4G. It's an untuned, ungrounded, end-fed, monopole in the form of parts of a metal frame.

There's also a large distinction between a "ground" and a counterpoise. A counterpoise is a part of the antenna system and may be earth ground in some situations. In RF, a ground is a connection to the earth. While there is some overlap in these definitions, your claim, that all antennas require a ground, was presumably referring to the earth ground, as described by your examples of broadcast towers and static buildups.

For a satellite, there's may be a counterpoise, but no (earth) ground. The counterpoise is unlikely because most satellites use circular polarization (to eliminate sensitivity to orientation), using spiral wound or pyramid shaped antenna structures that are matched to whatever the coax cable provides. The skin of the satellite is crammed with other antennas, solar cells, and sensors, that finding an area sufficiently large to be considered a metal counterpoise, is impossible.

The only thing really necessary for an antenna to function is the radiating element. Everything else is optional and depends on what you're trying to accomplish.

"Physic Principle An End Fed Half Wave Length Antenna is a variation of the much more common half wave length dipole antenna. When an antenna that is one half wave length long has RF energy applied to it at its resonant frequency a standing wave develops on it."

The earth is connected at the node. "A node is a point along a standing wave where the wave has minimal amplitude."

Does ""Large constructed half-wavelength dipole towers include the Warsaw radio mast - the only half-wave dipole for longwave ever built." needs the ground?
S*

It does NOT require a ground to be functioning, assuming the energy is
coupled into the radiator using some other way than an end-feed.

Of course it would be stupid to erect an over 600m high mast and not
connect it to ground, but that is for reasons entirely unrelated to
its use as a transmitter antenna.

Marconi was wrong.

You are stupid.  You cannot even grasp basic logic and reasoning.

When you read that a cow is an animal, you think that every animal
is a cow.

```

The tower insulated half way up and feed there are the two monoples.
It is the array.
But such are in form of the two monopole mast 1/4 wave apart.

Will be better to end the discussion.
S*

Szczepan Bialek <sz.bialek@wp.pl> wrote:

> Is the field electron emission from the tip top of antenna or not?

No.

Read this:

http://en.wikipedia.org/wiki/Field_electron_emission

Read all of it.

Then read it again until you understand it.

After you have mastered that, read this:

http://en.wikipedia.org/wiki/Corona_discharge

Read all of it.

Then read it again until you understand it.

After you have mastered that, read this:

http://en.wikipedia.org/wiki/Electric_arc

Read all of it.

Then read it again until you understand it.

If you can get this far, your question has been answered fully.

> I "do not know anything about Antennas, Transmitters. Feedlines, Matching,
> Efficiency,"

Obviously.

On 4/16/2012 5:16 AM, Ian Jackson wrote:

>
> To push and pull the current in and out of the capacitor, it was necessary to have a good, solid, zero-potential reference point, and the best one available was ground/earth (or, at sea, the hull of the ship). So, for the types of antennas being experimented with (and used) at the time, Marconi was absolutely correct.

Yep.. I think the frustration tends to be difficulty in understanding that it's just one type of system, and others that do not require any ground connection do exist.
Which means you would have to classify his statement as incorrect in the overall larger picture. I believe most have already stated that while some antennas do require such a connection, any "complete" antenna does not require one.

The vast majority of my antennas do not require any ground connection for proper operation.
Fer instance, I'm sitting out in the woods up at my recreational living center.. I have dipoles strung up in the trees which I leave there, and I roll the rg-58 coax up and hang it on a tree branch when I leave. Not a ground wire, or ground connection in sight.. And works perfectly well. Of course, you can't really see the wires here, but "S" can trust me, there is no ground connection. The radio is sitting on that stone bench, and the only connections are 12v to my car battery, and rg-58 coax feeding the dipoles. "I have 80 and 40 meter dipoles fed parallel with a single coax, and can slap a tuner on it, if I want to use some other band. " I have videos of this radio session using almost every band from 80m to 10m.. I went through each one seeing if they were active. They all were, up through 10m, on that day. If one wants to hear another band, just change the "80" in the url to "40", 20", "17", etc.. I think they should be on the server.. I think I missed 12m though for some reason.. Maybe no one was talking when I tuned it.. But it was open to somewhere, as I recorded Rarotonga Islands on 10m.

It wouldn't surprise me too much. Heck, I've been faked out more
than once when using cheap receivers, and picking up something that
was actually not on the frequency that I thought it was. :|

+1. great idea with easy construction, flexible mounting arrangements,
tunable after building, easy to locate parts, and straightforward theory/
results.

Correct.

One interesting counter-example, would be the simple one of a full-wavelength loop of wire, which is fed with a balanced feedline (twinlead or open-wire or ladder line), which is fed from a fully-balanced transmitter output stage (e.g. with transformer coupling from the driver transistors). To be extreme about it, let's say that the transmitter is itself based on a fully-balanced (differential) circuit, all the way back to the crystal oscillator. It's powered by a single battery, and is installed in a plastic chassic.

This sort of antenna would have no galvanic connection to "earth" at all. Measure the resistance or RF impedance between any part of the antenna or feedline structure, and *anything* not part of the antenna, and the result will be "huge".

Since it's a loop antenna, it has no "ends"... no points at which electrons could "fly off". The net current flow going up the feedline to the antenna will be zero, at all points - a positive current on one side of the feedline will be exactly balanced by a negative current on the other side of the feedline. There are no "excess" electrons or charge flowing in either direction.

You can even insulate the antenna wires, if you wish.

It will transmit just fine, with no connection at all to "ground". Disconnect the transmitter, install a receiver of a similar "balanced and isolated" design, and it'll receive just as well... again, with no connection to "ground".

I think he's the same guy who, for several years, has been posting
similar nonsense in various newsgroups. The script is usually similar,
typically "I have only a very basic knowledge of physics, but I know
that Einstein was completely wrong about his theory of relativity".

Well, this one usually goed more like "I read that in 1910 this result
was found in experiments, so everything we learned after that must
be completely wrong"...

Where is the car battery?
On the stone bench or in the car?

A loop antena have the antinodes. The points at which electrons could "fly off".

See Fig. 2: http://www.antiquewireless.org/otb/lodge1102.htm

>The net current flow going up the feedline
> to the antenna will be zero, at all points - a positive current on one
> side of the feedline will be exactly balanced by a negative current on
> the other side of the feedline. There are no "excess" electrons or
> charge flowing in either direction.

""A further feature of the structure of negative coronas is that as the electrons drift outwards, they encounter neutral molecules and, withelectronegative molecules (such as oxygen and water vapor), combine to produce negative ions. These negative ions are then attracted to the positive uncurved electrode, completing the 'circuit'.". From: Negative coronas. Mechanism.
http://en.wikipedia.org/wiki/Corona_discharge#Negative_coronas

In the each antenna is the excess/deficit of electrons and "charge flowing in either direction."
But the negative corona and the positive corona are not simmetrical.
At transmitting you have the deficit and at receiving the excess.
Without the earth the static build up and radio stop working.
>
> You can even insulate the antenna wires, if you wish.

Can you measure the static electricity?
>
> It will transmit just fine, with no connection at all to "ground".
> Disconnect the transmitter, install a receiver of a similar "balanced
> and isolated" design, and it'll receive just as well... again, with no
> connection to "ground".

You will transmit just fine if you have the ground/chassis/counterpoise.

> be completely wrong"...

I read that now:

""A further feature of the structure of negative coronas is that as the electrons drift outwards, they encounter neutral molecules and, withelectronegative molecules (such as oxygen and water vapor), combine to produce negative ions. These negative ions are then attracted to the positive uncurved electrode, completing the 'circuit'.". From: Negative coronas. Mechanism.
http://en.wikipedia.org/wiki/Corona_discharge#Negative_coronas

""The difference, then, between positive and negative coronas, in the matter of the generation of secondary electron avalanches, is that in a positive corona they are generated by the gas surrounding the plasma region, the new secondary electrons travelling inward, whereas in a negative corona they are generated by the curved electrode itself, the new secondary electrons travelling outward."

"in a negative corona the electrons are generated by the curved electrode itself".

Is the field electron emission from the tip top of antenna or not?

Where you learned that no field electron emission?
S*

We don't operate our antennas in the voltage range where that becomes
a problem, like Tesla did.

So it does not apply to amateur radio antennas.

His play-stupidity is indeed extremely inventive. There doesn't seem to
be anything that he can't mis-understand so well.

Hello Jeff.

I agree. It's nice to see there are some patient and helpful people on this NG who have tried to help S. I'm speculating on what sort of person he really is .. then I smile to myself when I see his circular arguments. I wonder what would happen if we posted items about him but didn't reply to his postings (similar to the "we're talking about you, not to you" behaviour".

I'll tell you one thing - the discussion about antennas has been very interesting so it's made the NG live up to its name.

73, Ian.

I doubt that he is a troll. Trolls usually show some intelligence in adapting their responses, so as to keep the fun going. This one simply fixates on a few sentences and appears unable to focus on anything out of the immediate context of the original sentence. This inability to shift focus to process new information is more a symptom of a cerebral handicap, something like Alzhheimer's or Asperger's diseases or even early-stage dementia. Unfortunately, there is not a great deal that medicine can do for these problems. Perhaps his keepers give him a computer to occupy his attention.

Internet newsgroups are wonderful (IMO), but there are not good mechanisms to prevent one or two people from destroying an otherwise excellent group. One can plonk the offender(s), but that still leaves all the responses visible. I wish people would simply cease responding to him, since it is a pointless exercise.

Bill

OK, there is also http://www.dxlabsuite.com/ which does rotor control, rig
control, QSO's, logging, DX spotting, award tracking, propagation, and
a bunch of other things.

No involvement, just a happy user.

> Do you mean "mast" or "aerial" when you say that the voltage is dobled
> (sic)?

Not dobled but doubled (twice as large). It is desribed by Lodge: See Fig.2
: http://www.antiquewireless.org/otb/lodge1102.htm
"The electrical waves produced by the oscillations at A traveled along the
wires and were reflected at the far ends. Lodge knew that the longer spark
at B3 was due to what he called the "recoil impulse" or "recoil kick" at the
end of the wires where the waves were reflected.[4] At spark gap B3 both the
incident wave and the reflected wave had their maximum values and were in
```

phase. This produced a voltage twice as large as the voltage at spark gap
A."
>
> "Tesla discovered that the one end of the dipole must be earthed to have
> the strong waves."

A dipole with one ene earthed becomes a monopole.
Hertz transmitter is a dipole. The Tesla's is a monopole.
Todays dipoles are simply the two monopoles.
Thanks this the waves are polarized.

But the question is if Marconi was right:"
"The necessity or utility of the earth connection has been sometimes
questioned, but in my opinion no practical system of wireless telegraphy
exists
where the instruments are not connected to earth."

Best regards,
S*

The problem with you is that you will not take the correct answer
to that question, but you will keep asking it until someone incorrectly
answers that Marconi was right.

Ian did it. He wrote:
"The "static to earth" in my HF aerial is merely to get the static to bypass
my receiver. The earth connection is not necessary in order to receive
signals."

Tell as if a practical radio exists where the instruments are not connected
to earth/chassis."
I am not asking for what: to bypass or to receive/transmit.

Polarization has nothing to do with whether an antenna is a monopole or a dipole.

No, he did not.

You are just too stupid to understand what it is that Ian wrote.

> Tell as if a practical radio exists where the instruments are not connected
> to earth/chassis."

Meaningless gibberish.

> I am not asking for what: to bypass or to receive/transmit.

More meaningless gibberish.

Hello Szczepan
No, I did not say that Marconi was correct. I did say that the earth
connection is not necessary in order to receive signals. I suspect that your
English is not as good as we think.

Hello again Szczepan .
You used the term "dobled". Was it a typing error on your part?
Are we discussing spark transmission and non-resonant aerials?

Regards, Ian.

Hello folks.

I have a suspicion that Szczepan's English is either not as good as it appears or that he is using a web translation page.

Szczepan - do you hold an amateur radio licence, please?

Regards, Ian.

Voltage is not product. The splendid, long sparks are.
What the sparks are made of?

I have even never seen a transmitter.
For me it is a "black box".

I only want to know if the box is connected to the earth/chassis.
```

Your the first answer was Yes ("The "static to earth" in my HF aerial is
merely to get the static to bypass my receiver).

Ionized air is rather lazy. What is the other constituent of sparks?
What "made" the ionization?

Hey Szczepan,

Spark transmitters are not used anymore.
Try to find some more recent articles about transmitting.

Today we use nicely synthesized carrier waves that are fed to antennas suitable for the frequency in use, not a noise generator and transformer to high voltages connected to a random wire net.

Especially when that frequency is somewhat higher (much higer than what Marconi and Tesla were transmitting on), there is no need for en earth connection or even a chassis.
That is because an antenna is used that is balanced or has its own counterpoise for the driven element.

A connection to earth would not be effective anyway, because antennas used at higher frequencies are often several wavelengths above the earth, and a wire used to connect to the earth would not behave like a conductor at those frequencies.

We also operate our antennas well below the point where arcing occurs, so we don't have to deal with electron emission.

So now please go off to a group that operates the century old techniques that you seem to be discussing.
Maybe you can find a Tesla coil enthousiasts group where your voice will be appreciated, although I think they are not using sparkgaps anymore either.

That his English is horrible is a given, but since he has been doing exactly the same thing for years now it should be a lot better than it is.

He has been posting the same idiotic crap for years to the sci. groups and getting the same responses.

He is incapable of comprehending that Tesla, Maxwell, Marconi, etc. did NOT have a full understanding of RF over a hundred years ago.

He keeps posting the same idiotic questions, with references to century old quotes, over and over no matter how many times he is answered.

> Szczepan - do you hold an amateur radio licence, please?

No, he does not.

Yes, it is. The purpose of a Tesla coil is to generate high voltages.

> The splendid, long sparks are.

Nope, the purpose is the high voltage, the sparks are a by product of a
high voltage.

The RF produced is a by product of the sparks.

> What the sparks are made of?
> S*

Electrons liberated by the HIGH VOLTAGE, idiot.

The high voltages produced by the Tesla coil.

Repeat this until it sinks into your thick skull: Tesla coils produce high
voltages.

Repeat this until it sinks into your thick skull: High voltages produce arcs.

Repeat this until it sinks into your thick skull: Arcs produce RF.

Repeat this until it sinks into your thick skull: Using arcs to produce RF
is an obsolete techonology and illegal in most of the world.

Hello Szczepan.
It seems that you totally misunderstood my answer.
A ground connection is NOT necessary in order to receive a signal.

You tell me that you have not seen a transmitter and regard it as a black
box. I recommend that you get a modern textbook on radio technology so that
you can understand how radios and aerials work.

Kindest regards, Ian.

Hello again Szczepan. I rarely ever use the term "chassis" and I don't
remember mentioning an earth on a radio.

For clarification - radios can and do transmit and receive successfully
without any connection to earth, either the actual ground or to an
artificial earth.

Kindest regards, Ian.

Good afternoon Szczepan.
You didn't answer my question about aerials.
Are you discussing resonant or non-resonant aerials, please?

Kindest regards, Ian.

Hello Szczepan.
A dipole with one end earthed wouldn't be a monopole.
http://en.wikipedia.org/wiki/Dipole_antenna
http://en.wikipedia.org/wiki/Monopole_antenna

Best wishes, Ian.

Is it necessary to "get the static to bypass my receiver".
>
> You tell me that you have not seen a transmitter and regard it as a black

For me is enough to know "Is it the ground/chassis/counterpoise necessary to
"get the static to bypass a transmitter/receiver".?
I hope that some of you know the answer.
```

I am not asking If "Does a ground connection is necessary in order to
receive a signal."

Best regards,
S*

> A dipole with one end earthed wouldn't be a monopole.
> http://en.wikipedia.org/wiki/Dipole_antenna

See: http://en.wikipedia.org/wiki/File:Dipole_antenna_in_meters.png

> http://en.wikipedia.org/wiki/Monopole_antenna

"One side of the antenna feedline is attached to the lower end of the
monopole, and the other side is attached to the ground plane, which is often
the Earth.

This contrasts with a dipole antennawhich consists of two identical rod
conductors, with the signal from the transmitter applied between the two
halves of the antenna.

Any comments?
Best Regards,
S*

Well I am going to be unusually kind today, since it is Sunday and also because I am going to show some intelligence here. So everyone listen up - because I am only going to do this one time.

I am not going to fight over who invented radio, or the different types of modulation scheme's - since the days of spark gap transmitters.

I tried to post some relevant information - but it seemed to get lost in the jumble.

The bottom line is - 3rd world countries and places such as the Soviet Union and their sattelite countries does not understand how communications works - to the extent that people in the free world does - because when you live in a communist society you are told what to think and how to think and so you cannot think for yourself.

When the day comes when someone emancipates you and you are free and all of a sudden there is no one telling you how to think or what to say - your mind goes beserk and you just start thinking about things that no one has thought about in 50 years - because even a infant has to crawl before it can walk and those people are so far behind the times it will take them a certain period of time to readjust to the way the rest of the world operates and so we have to be kind to people who were not born and raised in the USA and thinks that they are the worlds leading source of all information and that everything published on the internet is factual.

The Sattelite one was the one that really got me to thinking.
There is nothing in outer space for the signals to bounce off of - so they travel millions of miles in just a couple of seconds and you have to wonder if there is some other form of intelligence on another planet several galaxies away that is monitoring our simple form of communications - and probably laughing at us for what we say and how we act and what we do.
Rock n roll music is probably the most entertaining of all the types of transmissions we make - because it doesn't make much sense when some rapper repeats the same thing over and over again and other musicians plays the same 3 chords over and over again and people pays millions of dollars to buy their albums and listen to them at concerts or that we would allow someone to play advertising over the radio and not turn it off or turn the dial to another frequency.

Or that some ham would be willing to spend 10's of thousands of dollars to buy a transceiver that does the same basic thing as a AM radio you can buy in any Walmart or Goodwill for a couple of bucks.

When you crank up the power, it allows the person on the other end to use a smaller antenna - hence the people who buys or builds the big towers and the big beam antenna's would think that their investment would allow them global communications on a daily basis - and still we have not gotten past the fact that all reliable communicatiosn is LOS - even 100 years later...

The OP wanted to debate the fact that some antenna's works best when we include some type of ground. Yes a good vertical transmitting antenna includes some type of ground to keep the signal from warming the clouds and being wasted.
A beam antenna does not have a physical ground, yet still works - maybe the ground reflections helps the signals to travel further.
But we all know that effective communications requires the antenna to be as high as possible.
Only once you get to what is it 38,000 miles one antenna will transmit to one hemisphere - or is it what ever part of the earth you can see and will transmit no further.
That is the point of diminishing returns.

Why than: "The ideal ground system forAM broadcasters comprises at least 120
buried copper or phosphor bronze radial wires at least one-quarter
wavelength long and a ground-screen in the immediate vicinity of the tower.
All the ground system components are bonded together, usually by welding,
brazing or using coin silversolder to help reduce corrosion". From:
http://en.wikipedia.org/wiki/Monopole_antenna

Tell them that they are WRONG.

Now you have written it yourself! With a dipole antenna you do not
need an earth connection because the signal is applied between the
two halves of the antenna, not between earth and the antenna.

End of discussion.

It says "for AM broadcasters", not "for every transmitter".

Your conclusion that anything applying to a low frequency transmitter
for which it is impractical to build a balanced resonating antenna
applies to all transmitters in the universe is just wrong.

Real dipole needs:
"In the lower half of the mast, there was a vertical steel tube, attached to the mast's outer structure with large insulators. This tube was grounded at the bottom, and connected electrically to the mast structure by an adjustable metal bar at 328 metres.[2] This technique allowed adjusting the impedance of the mast for the transmitter and worked by applying a DC ground at a point of low radiofrequency voltage, to conduct static charge to ground without diminishing the radio energy. Static electrical charge can build up to high values, even at times of no thunderstorm activity, when such tall structures are insulated from ground. Use of this technique provides better lightning protection than using just a spark gap at the mast feed, as is standard at most mast radiators insulated against ground."

No.

Read this:

http://en.wikipedia.org/wiki/Field_electron_emission

Read all of it.

Then read it again until you understand it.

After you have mastered that, read this:

http://en.wikipedia.org/wiki/Corona_discharge

Read all of it.

Then read it again until you understand it.

After you have mastered that, read this:

http://en.wikipedia.org/wiki/Electric_arc

Read all of it.

Then read it again until you understand it.

If you can get this far, your question has been answered fully.

Hello Szczepan.

No, it is not necessary to ge the static to bypass a receiver.

> For me is enough to know "Is it the ground/chassis/counterpoise necessary
> to "get the static to bypass a transmitter/receiver".?
> I hope that some of you know the answer.

Same answer. It is not necessary ...

Kindest regards, Ian.

Hello Szczepan .
Dipole has two pieces of metal.
Monopole has one piece of metal.
Connecting a dipole to ground doesn't remove one piece of metal.

Best wishes, Ian.

Hello again Szczepan
The answer to your question is in that Wikipedia article. Read the
"Radiation Pattern" paragraph.

If you can get ham radio textbooks in your country then you'd understand a
lot better by reading a textbook on aerials.
Try www.rsgbshop.org/acatalog/Online_Catalogue_Antennas_37.html
and www.arrl.org/shop/Antennas/

I haven't seen an answer from you to my question which asked:
"Are you discussing resonant or non-resonant aerials, please?"

Best wishes, Ian.

Good evening Szczepan.

The Warsaw radio mast was not a dipole.

May I remind you that I would appreciate an answer to my question "Are you
discussing resonant or non-resonant aerials, please?". It would help to
clarify what you have in mind,

Kindest regards;
have a good evening,
Ian.

That is not a dipole.  It is a vertical half-wave radiator.  It is
not center fed like you discussed above.

Because they are talking specifically about a vertical, monopole antenna mounted on the ground and fed at the base end.

They are NOT talking about antennas in general.

They are NOT talking about transmitters.

> Tell them that they are WRONG.
> S*

They are not wrong, you are just too stupid to understand what they ARE talking about.

```

# Why than: "The ideal ground system forAM broadcasters comprises at least
120
# buried copper or phosphor bronze radial wires at least one-quarter
# wavelength long and a ground-screen in the immediate vicinity of the
tower.
#  All the ground system components are bonded together, usually by welding,
# brazing or using coin silversolder to help reduce corrosion". From:
# http://en.wikipedia.org/wiki/Monopole_antenna
#
# Tell them that they are WRONG.
# S*

Looks like you are either a troll or being deliberately dense.  Reminds me
of the mechanical engineer guy on the group a while back who was making
fantastic claims for miniscule antennas.

At any rate:

But it is Marconi's opninion. It is not the truth, it is only an
opinion. When you like, you can say he was "not right". Or you can
just respect that he had this opinion. Your choice.

So we can move on.   What is your next question about 1910's scientists?

> So we can move on.   What is your next question about 1910's scientists?

It may be more accurate than you are giving him credit for. It was based
upon the antenna designs and frequency ranges in use at the time.

All I know is that by the end of WWI, 200 meters was considered to high in
frequency to be useable, which is why the US Navy wanted hams to be limited
to frequencies above it (or wavelengths below it).

The early practical groundless antennas were 1/2 wave, either a dipole or end fed half wave, and is a 100 meter wire practical? A 1000 meter?

What frequencies (or wavelengths) was he speaking about?

To answer the comment about cell phones, modern ones operate at around 2.1gHz (3G) a frequency that was impossible to produce at the time.

PL-259 connectors are called UHF connectors for a reason, when they were designed 30mHz was UHF. And that was 30-40 years later.

Geoff.

Is even one textbooks where is wrote that Marconi was WRONG?

Are your transmitters without any earth?

I am checking from time to time if your knowledge have moved on.

Hello Szczepan.

In general, you seem to be looking at outdated techniques and technology.

I guess if you were considering photography you would be asking if wet plates were still in use and what would be a recipe for a good emulsion. Of course, film stopped using wet emulsion a century (or more) ago. Wet emulsion wasn't wrong at the time but it definitely is obsolete.

If you were considering car technology you might be asking about manual ignition advance/retard. It had its uses but was automated decades ago and most drivers will not be aware of it. Same thing applies to the choke.

My radio doesn't need to be connected to ground/earth other than for static/lightning reasons. The theory and technology of radio have made a lot of progress since the time of Marconi.

Hope this is of some help.
Kindest regards from the UK,
Ian.

Yeah, it was thought that a long time ago and it has since been proven
to be wrong, as you have been told several times now.

Which means it is true for specific, limited cases, but not true in general.

There has been a lot learned about electromagnetic theory in the past
100 years that this babbling idiot just ignores.

> Is even one textbooks where is wrote that Marconi was WRONG?

Yes, every modern textbook on electromagnetic theory.

See Electromagnetics by Kraus and Carver, Chapter 14, Antennas and Radiation
as but one example.
```

> Are your transmitters without any earth?

Yes, some of them are, some of them aren't.

> I am checking from time to time if your knowledge have moved on.
> S*

You are just babbling because you can not accept the fact that a lot was
learned after Marconi died, some of which is in direct contridiction to
some of the things he thought were true at the time.

My understanding is that in this context, "UHF" is not an acronym for
"ultra-high frequency". It means "Universal High Frequency"... as in,
can be used for all "high frequency" applications.

Thanks Dave, in all the years I have been interested in radio I never heard or read that. It does clear up a lot of questions. :-)

73,

Geoff.

Hello Ian,

So the earth is necessary in your radio for the static reasons.
In my also:
"In the lower half of the mast, there was a vertical steel tube, attached to the mast's outer structure with large insulators. This tube was grounded at the bottom, and connected electrically to the mast structure by an adjustable metal bar at 328 metres.[2] This technique allowed adjusting the impedance of the mast for the transmitter and worked by applying a DC ground at a point of low radiofrequency voltage, to conduct static charge to ground without diminishing the radio energy. Static electrical charge can build up to high values, even at times of no thunderstorm activity, when such tall structures are insulated from ground. Use of this technique provides better lightning protection than using just a spark gap at the mast feed, as is standard at most mast radiators insulated against ground."
From: http://en.wikipedia.org/wiki/Warsaw_radio_tower

It seems to me that the same reasons were in Marconi times.

So I repeat my question:

""The necessity or utility of the earth connection has been sometimes questioned, but in my opinion no practical system of wireless telegraphy exists
where the instruments are not connected to earth."(Marconi in 1909).

It is still true?
S*

You have a big problem with comprehending, don't you?

Earlier you wrote that Marconi said that a capacitive coupling to ground was good for HF grounding and now you want DC coupling to discharge static electricity. Those two reasons for grounding are completely different.

> So I repeat my question:

Why do you repeat your question? It has been answered so many times already.

Radio on the Moon has the "earth connection". The Moon is smaller than the
Earth.
Do you think that "the earth" must be giant?

Your mobile phone has earth connection, radio on satellites and planes
have earth connection because they are on the chassis. Accept this and
move on.

All must have.

>Some have them in order to work correctly, some have them for protection

All must have for protection against the build up of static.
"Static electrical charge can build up to high values, even at times of no thunderstorm activity,"
